NUMBER 1

HEMOLYTIC STREPTOCOCCAL INFECTIONS WITH SPECIAL REFERENCE TO PROGNOSIS AND TREATMENT WITH SULFANILAMIDE

CHESTER S. KEEFER, M.D.*

BOSTON

IN EVALUATING the therapeutic effectiveness of any method of treatment of an infectious disease, two procedures can be used. First, it can be determined whether the treatment reduces the fatality rate in a large number of cases; secondly, it is often possible to decide whether the course of the disease can be shortened or altered and certain of its features prevented. In evaluating data, it is necessary to consider all the factors which influence the fatality rate, particularly the patient's age. It is sometimes exceedingly difficult to decide whether the course of an infectious disease has been changed by treatment. In diseases that are self-limited in their course, this is much easier than in those diseases in which the course is indeterminate. For example, it is well known that uncomplicated scarlet fever or erysipelas may have a course of from seven to ten days of fever, when recovery rapidly takes place. In puerperal sepsis, mastoiditis or cellulitis the duration of the condition may vary widely, so that it is impossible to predict how long the infection will persist under conditions which do not call for surgical or other types of treatment.

In order to obtain more information concerning the relative importance of various factors in the case fatality rate of hemolytic streptococcal infections, I have summarized certain important features, including age, type and location of the lesion, the presence or absence of bacteremia or debilitating disease, and the type of treatment.

It is now commonly recognized that the mortality in hemolytic streptococcal infections is highest in the first, third and seventh decades. This corresponds respectively to the peaks of incidence of infections occurring in the throat, of puerperal infections and of infections such as cellulitis and

erysipelas. In the first decade, the highest incidence of death is seen in infants and children under four, especially when there is erysipelas or middle-ear and mastoid disease with its intracranial and other complications. In the cases of puerperal infection, the death rate is highest in those with peritonitis, with thrombophlebitis and with bacteremia. With erysipelas the seriousness of the

Figure 1

A Percentage distribution according to age of 200 000 cases of scarlet fever in Massachusetts

B Mortality rate of scarlet fever per 100 000 population at various ages

C Percentage of cases of hemolytic streptococcal bacteremia arising from throat infections

D Percentage of fatal cases from Group C

infection increases with age. In general, it may be said that streptococcal infections are most serious at the two extremes of life—in the very young and in the aged. The location of the infection at various ages, however, plays a significant part and must be taken into account.

Read before the combined clinical meeting at the annual meeting of the Massachusetts Medical Society, Boston, June 2, 1937.

From the Thorndike Memorial Laboratory, Second and Fourth Medical Services (Harvard), Boston City Hospital, and the Department of Medicine, Harvard Medical School, Boston.

Associate professor of medicine, Harvard Medical School.

Infections of the Throat and their Septic Complications Figure 1 illustrates the incidence of these infections at various age periods and the mortality per 100,000 population. It also shows the age distribution of bacteremia and its case fatality. The facts to be gathered from Figure 1 are as follows: The highest fatality rate is under four years of age, this despite the fact that the age of highest incidence of hemolytic streptococcal infection is between five and fifteen. The form of the curve for bacteremia resembles the curve of incidence of the diseases, but the fatality rate is less in patients over four years than in those under four. The infection is also much more serious when there are complicating conditions such as acute mastoiditis and lateral sinus thrombosis.

Erysipelas and Cellulitis The fatality rate in erysipelas is about 15 per cent. This varies, however, with age, as shown in Figure 2. It is highest

Figure 2. Age distribution and case fatality rate in 1400 cases of erysipelas. The small numbers in the first decade indicate months and years, that is, 0-6 and 6-12 represent months, 12 and 3-9, years.

under six months and lowest from ten to fifty years. After fifty it rises with advancing age, so that it almost reaches its former level. This is due in part to its occurrence in patients with debilitating diseases. Approximately 70 to 90 per cent of individuals with bacteremia and erysipelas die.

Puerperal Sepsis The fatality rate in hemolytic streptococcal puerperal sepsis varies among different clinics from 15 to 30 per cent. When the blood cultures are positive, the rate is about 50 per cent, when they are negative, about 20 per cent. In most of the latter cases death results from peritonitis or thrombophlebitis. It would appear, then, that the most favorable cases are those with a negative blood culture and no signs of peritonitis or pelvic phlebitis, and that the most unfavorable cases are those with bacteremia with or without

peritonitis or thrombophlebitis. Of the cases with bacteremia, the favorable ones are those in which the blood stream can be cleared with or without the subsequent development of a localized abscess.

Bacteremia A recent survey of 246 cases of hemolytic streptococcal bacteremia¹ showed that bacteremia is always of grave prognostic significance, the fatality rate was 72 per cent. There was a tendency for bacteremia to increase in seriousness with advancing age, and whenever it occurred during the course of erysipelas or cellulitis the fatality rate was high. It was somewhat lower in puerperal sepsis, and lowest of all in the first two decades of life and when the primary infection was situated in the throat, middle ear or mastoid processes. A summary of the fatality rates with different primary infections is given in Table 1.

Table 1. Summary of Total Number of Cases with Bacteremia and Infection in Various Locations.

PRIMARY INFECTIONS	TOTAL NUMBER OF CASES	TOTAL NUMBER OF FATAL CASES	PER CENT DEATHS
Throat, middle ear and mastoid in fections including lateral sinus cavernous sinus and tonsillar vein thrombosis	69	38	55
Pelvic infections	41	23	56
Cellulitis and erysipelas	61	49	80

When recovery follows a demonstrable hemolytic streptococcal bacteremia it can be shown that the blood is invaded for a relatively short period and is then cleared of organisms, with or without the subsequent development of focal metastases in various organs. Where such metastases can be adequately treated by surgical methods, recovery usually takes place. When death occurs there has usually been (1) a rapidly progressive bacteremia without focal metastases, (2) focal metastases in areas such as the endocardium or meninges, or (3) multiple abscesses which cannot be treated by surgical methods.

We have been able to correlate the above findings with the immune reactions of the patient, as follows. In rapidly advancing bacteremia, no antibodies can be found in the circulating blood by the methods that we have used. When the blood is cleared of organisms, antibodies can be demonstrated, and in the cases with focal metastases and secondary waves of bacteremia they can be found in the circulating blood. It may be assumed, then, that bacteremia indicates a loss of equilibrium between the normal clearing mechanism for bacteria and the local defense mechanism.

The prognosis in hemolytic streptococcal infection evidently depends on the summation of such factors as age, location of infection, bacteremia, the presence of focal metastases that can be treated adequately, and debilitating diseases.

The method of treatment depends upon whether the manifestations of the infection are toxic or septic. The former are best illustrated by scarlet fever, in which it is now agreed that the rash, the febrile reaction (in part) the associated symptoms of infection, the enanthem and the faucial edema are caused by the exotoxins (erythrogenic toxins of the organism), it is also well recognized that these symptoms can be effectively treated by the use of scarlet fever antitoxin or potent convalescent serum. When patients are treated early and with adequate amounts of antitoxic serum, there is a fall of the temperature, frequently by crisis, six to twelve hours after its administration, a fading of the rash, a rapid disappearance of many of the symptoms of the infection, and a diminution of the faucial edema. In many cases the manifestations, both local and general, disappear in four or five days. No one who has witnessed these results can doubt the efficacy of this type of treatment. Nevertheless physicians often hesitate to use antitoxic serum. Their reasons are that the disease is frequently so mild that the serum is unnecessary, that the sickness which follows its administration is frequently severe and uncomfortable, and that general agreement that it prevents septic complications is lacking. Of these objections, the last is the most important. There is a fair amount of testimony that in certain clinics at least, the complications are fewer in the serum-treated cases than in the untreated ones, and while it will be generally admitted that these complications cannot be abolished, the evidence is sufficiently convincing to encourage one to use serum more freely in this disease. This is especially true for cases in the age period when the disease is likely to be most serious, namely, when the patient is less than five years of age, and where, regardless of age, there is a sharp febrile reaction with a faucial edema. To avoid serum sickness and horse serum sensitivity, convalescent serum may be used.

The ultimate goal in the treatment of septic features is to localize the infection, suppress the growth of organisms and finally destroy them. Our information concerning all the factors that favor such localization and destruction is woefully incomplete, but there are excellent grounds for believing that both a local and a general defense mechanism are brought into play. We know, for example, that focalization of an infection generally indicates an efficient local defense mechanism, and this, in turn, is dependent in large part upon the development of specific immune bodies. This can be amply demonstrated in many infections, that is, an infection can frequently be prevented from spreading and the blood stream cleared of organisms by the use of specific antibacterial

serum. When focalization occurs spontaneously and the blood stream is cleared, bacterial antibodies are usually demonstrable.

There are no type-specific antibacterial serums available for general use in hemolytic streptococcal infections. The use of antibacterial hemolytic streptococcal serum has been unsatisfactory because it lacks specific antibodies. To meet this deficiency, Lyons² has urged the use of immune blood transfusions from donors who possess antibodies against the particular strain of infecting organism. This method is sound, and is undoubtedly of great benefit for patients with bacteremia. Its only disadvantage is the time required in finding a suitable donor, in addition, technic for this is such that it requires someone with considerable experience to carry out the tests.

Other methods that have been used in the treatment of these infections are those of chemotherapy. The most recent one which gives promise is the use of sulfanilamide. The historical development of this drug is described in excellent summaries by Colebrook and Kenny^{4, 5} and Long and Bliss⁶.

It is well to review briefly the facts that are known about this drug as regards hemolytic streptococcal infections. It has been shown that it is not bactericidal when added to ordinary culture media, it is, however, bacteriostatic. When it is added to whole blood of men or monkeys, blood bactericidal power is increased, the same result can be accomplished in human beings by the oral administration of the drug.³ I have been unable to increase the bactericidal action of human serum by adding sulfanilamide but have effected it in some cases by adding it to whole blood.

The drug will save and prolong the lives of mice infected with many lethal doses of hemolytic streptococci, when the drug is withheld the animals die. Insofar as man is concerned, the most convincing evidence of its beneficial action rests in the 5 cases of hemolytic streptococcal meningitis^{7, 8, 9} in which the patients have recovered following its use, and there is strong evidence that it is beneficial in puerperal infections with and without bacteremia.^{4, 5}

I now present the results of my own experience with this drug in the treatment of 9 cases of hemolytic streptococcal infection with bacteremia, and of 8 cases of localized infection without bacteremia. This number of cases is too small for statistical analysis, but it indicates the trend of results.

The cases with bacteremia are summarized in Table 2, Figures 3 and 4 illustrate the clinical course of 2 patients with the disease who recovered. Figure 5 illustrates the course of 1 fatal case. The fever persisted in these cases from three to eighteen days after the drug was first given. The total amount administered varied from 18 to 58 gm.

ulating blood of man, Marshall has found that it is necessary to give approximately 0.066 gm per kilogram of body weight. After a single large dose has been given by mouth, the drug reaches

Figure 5 Temperature chart and course of disease of patient (Case 7) with thrombophlebitis of the right internal jugular vein with a submaxillary abscess and bacteremia with subcutaneous abscess. mately 10 mg per cent, it is necessary to continue administration at four-hour intervals. For these reasons, we have given the drug in accordance with the following plan. An initial dose of 0.6 gm per kilogram was given immediately, and this was followed by 0.6 gm every four hours until the temperature became normal. The drug was continued for an additional three or four days. In

many of our patients, therefore, 4 gm was given immediately, and an additional 4 gm during the next twenty-four hours and on each succeeding day. With each dose of sulfanilamide, 1 gm of sodium bicarbonate was added to prevent the excessive loss of base in the urine.

Marshall, Emerson and Cutting¹⁰ have studied the toxicity of the drug in animals, and in general they have found that it is relatively nontoxic. Certain symptoms due to it have been noted, such as malaise, headache, weakness and loss of energy. Anorexia and nausea with occasional vomiting also occur. Cyanosis of the skin and mucous membranes is observed in practically all cases when large doses are given, and unless sodium bicarbonate is administered coincidentally mild acidosis follows. Skin eruptions occasionally appear after several days, and they have the characteristics of a

Figure 6 Puerperal sepsis without bacteremia (Case 4). Temperature returned to normal two days following the beginning of treatment with prontosil solution.

pleomorphic maculopapular eruption of a morbilliform character. Fever also may be associated with the skin lesion.

A few cases of acute hemolytic anemia with hyperleukocytosis, jaundice, hepatomegaly and splenomegaly have been reported. All these patients recovered promptly following blood transfusion.

The drug being eliminated in the urine, it is well to limit its amount in patients with renal insufficiency, since in such cases it accumulates in the blood and tissues. Furthermore, since it contains the benzene ring, it is wise to do repeated leukocyte counts to detect any signs of agranulocytosis.

SUMMARY

1. The prognosis in hemolytic streptococcal infection depends on the summation of such factors as the age of the patient, the location and extent of the local lesion, the presence of debilitating dis-

eases, and the presence or absence of bacteremia. The type of treatment and the availability of the local lesion for surgical treatment are also highly important.

2 The highest fatality rate is observed in patients under five or over fifty.

3 Puerperal infections and cellulitis are usually more serious than infections arising in the throat.

4 The presence of such debilitating diseases as arteriosclerotic occlusion of the blood vessels of the extremities, diabetes, tuberculosis, cirrhosis of the liver and chronic nephritis always increases the mortality rate.

5 When bacteremia is present, the fatality rate is in the neighborhood of 70 per cent. It is highest in patients with cellulitis and erysipelas, slightly lower in puerperal sepsis, and lowest in infections arising in the throat, middle ear, and mastoid processes during the first two decades.

6 Treatment with antitoxin is most effective in young patients who have scarlet fever associated with high fever, faucial edema and the signs of profound intoxication.

7 Immune blood transfusions are helpful in infections with bacteremia where there is no sign of a localizing process.

8 Sulfanilamide is effective in delaying the death of mice infected with many lethal doses of hemolytic streptococci. Insofar as the infections

in man are concerned, the most suggestive evidence that this drug has a beneficial effect are the cases of hemolytic streptococcal meningitis which have recovered following its use, and the cases of hemolytic streptococcal bacteremia which it has favorably influenced. A more precise definition of its field of usefulness must wait upon a longer experience.

The sulfanilamide used in these cases was supplied by Winthrop Chemical Company and by Merck and Company, Inc. The prontosil solution was supplied by Winthrop Chemical Company.

ENCEPHALOGRAPHY IN THE DIAGNOSIS OF SUBDURAL HEMATOMAS

An Analysis of 35 Cases

THEODORE J. C. VON STORCH, M.D.,* AND DONALD MUNRO, M.D.†

BOSTON

DIAGNOSIS and treatment of subdural hematomas are becoming increasingly important problems in this age of alcohol, automobiles and accident insurance. One¹ of us in a recent article on this subject stated that in his experience "the diagnosis of subdural hemorrhage can be made only by exploration." He also noted that "encephalography and ventriculography have both been successfully used as diagnostic measures." Horrax and Poppen,² speaking of the chronic variety, say that "if there is any real question of a subdural hematoma, an encephalogram may be performed instead of the taps."

The term "subdural hematoma" embraces acute and chronic forms, the now antiquated pachy-

meningitis hemorrhagica and that vague entity, hydrops of the subdural space. It is now generally accepted that the pathologic picture of chronic subdural hematoma is but a late variant of the acute phase, and that at the late stage the hematoma may be liquid or solid or both, depending upon the osmotic interrelations that have been formed.¹

LITERATURE

Very little reliable evidence has been presented concerning the encephalographic diagnosis of subdural hematomas, this little is of no practical value because of its rarity. Many reports concerning the encephalographic picture after cranial trauma have appeared. Several of these contain pictures and case records suggesting that subdural hematomas were present but unrecognized by the authors.^{3-5, 6-8} None, however, are conclusive.

This material was prepared with the assistance of Works Progress Administration Project No. 6148-1047 for the study of alcoholism, Boston City Hospital.

*Junior visiting neurologist, Boston City Hospital.

†Surgeon-in-chief for Neurosurgery, Boston City Hospital.

Single cases of large calcified subdural hematomas have been reported by Goldhahn⁹ and by Critchley and Meadows¹⁰. In the former case, encephalography showed a large, single, calcified cyst compressing the homolateral ventricle and displacing it to the opposite side. In the latter, the mass was demonstrated roentgenographically without air injection. Both were proved by pathological examination.

Wartenberg¹¹ in 1926 successfully utilized encephalography in the differential diagnosis between subdural hematoma and cerebral neoplasm, the hematoma being confirmed at necropsy. Jochims¹² reported a case diagnosed by suboccipital insufflation of air. Dickerson¹³ reported another diagnosed by encephalography and confirmed at operation. Lindemulder¹⁴ reported still another in which encephalography was successful after ventriculography had failed. Grant¹⁵ described a chronic subdural hematoma as one of thirty-one verified brain tumors demonstrated by encephalography. Balado and Morea¹⁶ published 4 cases in which encephalography demonstrated subdural hematomas. In 3 of these intraventricular lipiodol was used as well as air.

Dyke¹⁷ has recently described a rare but pathognomonic encephalographic sign of subdural hematoma. This is a fingerlike subdural air shadow which lies over the hemisphere. He says that a similar but undiagnosed picture appeared once before in the literature. Even if pathognomonic, such a sign is found too infrequently to be of practical value.

All the above reports concern encephalographic demonstration of large solid chronic subdural hematomas which had produced gross alterations of the ventricular system.

Holt and Pearson¹⁸ have presented 3 cases in which an encephalographic picture of bilateral subdural air was associated with bilateral subdural fluid hematomas found later at operation. They believe that bilateral subdural air is suggestive of the condition. They consider this diagnosis even more probable when subdural air is associated with small ventricles, and feel that it is pathognomonic when a subdural cyst is outlined. On the other hand, Lemere and Barnacle¹⁹ have demonstrated subdural air in 20 per cent of 800 encephalograms (12 per cent bilateral, 6 per cent unilateral, 2 per cent subtentorial). If Holt and Pearson are correct, their conclusions would suggest that in an improbably large percentage of the 632 psychopathic cases reported by Lemere and Barnacle the patients were suffering from chronic subdural hematomas. Allen and associates²⁰ found subdural hematomas in only 7.9 per cent of 3100 consecutive autopsies on psychotic patients. It is

likely, therefore, that subdural air may appear in many cases in which there are no hematomas.

METHODS AND MATERIALS

Air injections were performed in all cases as a diagnostic aid. Three ventriculograms and thirty-two encephalograms were performed on 35 patients. The great majority of the encephalograms were done by the automatic simultaneous replacement method.²¹ Air was used in all cases. Except three x-rays not taken in this clinic, all roentgenography was performed with the patient sitting erect throughout the procedure. Encephalographic diagnoses were made first without reference to the case history and were later rechecked with respect to the clinical findings. Removal of the hematomas was accomplished according to the technique described by Munro.¹

Major preoperative diagnoses were as follows: subdural hematoma suspect 18, posttraumatic syndrome 12, posttraumatic epilepsy 11, brain tumor suspect 8, hysteria 4, focal or Jacksonian epilepsy 3.

RESULTS

Twenty-two patients were operated upon and discharged later with the following diagnoses: chronic subdural hematoma 7, chronic fluid subdural hematoma 9, extradural hematoma 1, subdural hematoma (?) 2, subpial cysts 1, posttraumatic syndrome 2.

In this group nineteen encephalograms were successfully performed and three ventriculograms were attempted. Two of the three ventriculograms were unsuccessful. The results are summarized in Table 1. It will be seen that 13 out of 22 cases

Table 1 *The Diagnostic Value of Encephalography and Ventriculography in 22 Patients Explored for Subdural Hematomas*

STATUS	SOLID SUBD HEM	FLUID SUBD HEM	TOTALS
Correctly demonstrated	5	1	6
Correctly suggested	2	3	5
Correctly excluded	1	1	2
Not present when diagnosed	1	1	2
Not shown when present	0	5	5
Inadequate x rays	1	1	2
Total	10	12	22

(60 per cent) were correctly diagnosed, 7 (30 per cent) incorrectly diagnosed, and 2 (10 per cent) undiagnosed because of inadequate ventriculography. A separate analysis of the solid and fluid hematomas is much more significant, however. Eight out of 10 cases (80 per cent) with the solid type were correctly diagnosed, 5 being definitely demonstrated in the films. On the other hand, only 4 out of 12 (33 per cent) with fluid hematomas were correctly diagnosed, and in 5 others the films failed to show fluid which was subsequently demonstrated

at operation. There were, however, only 2 cases in the series in which operation failed to reveal a hematoma when encephalography had suggested its presence. These observations suggest that encephalography may be of value in demonstrating and localizing solid subdural hematomas but is of little value in cases with fluid hematomas.

Subdural rather than subarachnoid air appeared over the hemispheres in 6 or 22 cases (27 per cent). It was found in 3 of the 5 cases in which a definite diagnosis of solid hematomas was correctly made, and in 1 of the 2 cases in which the diagnosis was suggested by the encephalographic films. It was considered, correctly, to suggest the diagnosis in 1 out of 5 cases of fluid hematoma, but led to an erroneous diagnosis of fluid hematoma in 1 case in which exploration later revealed no accumulation of fluid. It is therefore apparent that subdural air over the hemispheres may be associated at times with subdural hematomas, but does not have any great diagnostic significance.

One ventriculogram and twelve encephalograms were performed successfully in 13 patients in whom the clinical diagnosis of subdural hematoma was suspected but on whom operation was not performed. In 7 of the 13 cases (54 per cent) the encephalographic studies were thought to exclude the possibility of subdural hematoma. Encephalograms in the remaining 6 cases suggested the presence of hematoma but exploration was not performed, either because of contradictory clinical evidence or because of refusal by the patient. Additional subdural air over the hemispheres was seen in 4 of the 6 cases with encephalograms which had suggested the presence of subdural hematoma.

Since no operations were performed in this latter series, the impressions derived from encephalography are not susceptible of proof. They are presented merely to demonstrate the use of encephalography in cases in which subdural hematomas are suspected. This procedure in experienced hands, however, may be of great assistance in such cases.

DISCUSSION

Cranial roentgenography is of little value in the diagnosis of subdural hematomas. The presence or absence of a cranial fracture has no bearing on the subject. No pathognomonic bone changes have been observed. The visualization of a displaced, calcified pineal gland following cranial trauma is merely suggestive evidence. Demonstration of a calcified subdural hematoma has been reported in only 3 cases, 1 having been seen in this clinic.

Encephalography appears to be of more diagnostic value. Gross compression of all segments

of one lateral ventricle, combined with a shift of the entire ventricular system to the opposite side and homolateral obliteration of the sulcal shadows, is indicative of a large flat intracranial mass. The encephalogram, however, identifies it as no more than a mass and is not diagnostic of hematoma. Furthermore, such a picture is found infrequently, and then only in cases of large, well-organized subdural hematomas.

A more practical application of encephalography is in the diagnosis of the commoner types of clot. These are the mixed and fluid varieties. In these cases the encephalographic picture appears to be quite variable. Frequently it is but little altered from the normal. As no clear-cut formulation of the pathologic appearance is possible, the diagnostic value of the encephalogram depends largely upon the knowledge and experience of the interpreter. With this reservation in mind, the variations from the normal, in order of their diagnostic importance, are as follows:

1. A slight but definite depression of the roof of one lateral ventricle associated with or without a shift of the ventricular system (and often the falx) to the side opposite the depressed ventricle, a slightly enlarged contralateral ventricle, variable contralateral hemispheric changes, and some decrease of the homolateral hemispheric markings.

The diagnosis of subdural clot is favored by complete absence of air in the subarachnoid space above the sylvian fissure homolateral with the depressed ventricle. It is important to remember that enlargement of one ventricle often makes the other ventricle by comparison appear to be depressed and flattened as from above. When ventricular shift is not present the picture is easily confused with that of moderate unilateral hemispheric atrophy, especially if there is an excess of hemispheric air on the side of the enlarged ventricle.

2. Small multiple or large single cystic areas of subdural hemispheric air associated with normal or moderately enlarged ventricles and variable subarachnoid hemispheric air.

It is essential that the cystic areas be fixed in position so that the air does not shift during the various cranial positions assumed during the making of the encephalogram. Such a picture is usually associated with durarachnoid adhesions.

3. No depression or distortion of the ventricle but an absence of subarachnoid hemispheric air on one side associated with a contralateral ventricular enlargement.

4. Unilateral subdural hemispheric air with contralateral ventricular enlargement.

Such collections of subdural air are capable by themselves of depressing and distorting the homolateral ventricle. This type of ventricular distortion is not, therefore, indicative of a mass.

5. Bilateral subdural hemispheric air with variable ventricular alterations, depending upon the amount and distribution of the air.

Freely motile subdural air over the hemispheres may be associated with subdural hematomas, but is certainly not diagnostic. It occurs much too frequently in routine examinations of patients in whom an equal percentage of hematomas is unlikely, as shown by the figures given by Holt and Pearson,¹⁸ Lemere and Barnacle,¹⁹ and Allen, Daly and Moore.²⁰ Subdural air is also a very common finding in roentgenograms taken twenty-four hours or more after encephalography. Air which has been demonstrated solely in the ventricular and subarachnoid spaces can become largely concentrated in the subdural space over the hemispheres in from ten minutes to as many hours. Whether this indicates a fragile pathologic arachnoid is not yet clear. It is certain that air may be introduced into the subdural space at the lumbar level, during the air injection. In these cases it certainly cannot have any pathological significance. Furthermore, the compression caused by subdural air often results in a ventricular compression which has been mistaken for pathologic ventricular alteration. It is therefore unwise to consider the presence of unencysted subdural air as diagnostic or even suggestive of the presence of a subdural hematoma until the significance of air in the subdural space is more thoroughly investigated. Such investigations will be reported in a subsequent paper.

CONCLUSIONS

Ordinary cranial roentgenography is of little value in the diagnosis of subdural hematomas. Demonstration of a pineal shift following cranial trauma merely suggests the presence of a mass which may or may not be a clot.

Encephalography is rarely diagnostic of subdural hematomas, and then only in cases with large chronic clots. The value of encephalography in the diagnosis of fluid hematomas appears to be negligible. Until further information is available it is unwise to lay too much stress upon the presence of unencysted subdural air as an indication of the presence of a subdural hematoma.

On the other hand, it has been demonstrated that encephalography is a valuable adjunct in the diagnosis of thin, solid subdural hematomas. It is in such cases, in which the history and examination are often inconclusive, that an experienced encephalographer may offer invaluable assistance to the neurosurgeon.

In the final analysis we continue to believe that a *definite* "diagnosis of subdural hemorrhage can be made only by exploration."

RECTAL EVIPAL SODIUM AS A BASAL ANESTHETIC IN UROLOGIC SURGERY

JOHN H. HARRISON, M.D.,* AND JOHN E. DUNPHY, M.D.†

BOSTON

THE advantages of a basal anesthetic are well established, particularly in nervous and excitable patients, as well as in those for whom a very light inhalation or local anesthetic is indicated. Avertin, which has proved very satisfactory for this purpose, is frequently contraindicated in urologic surgery because of the high percentage of patients with renal insufficiency. Following the lead of Gwathmey,¹ who has shown that evipal sodium is effective when administered by rectum, we have given this new anesthetic a clinical trial in urologic surgery. The results in 40 cases have been very gratifying.

The age incidence of the patients in this series has varied from twelve to seventy-five. Six patients were in the second decade, 6 in the third, 5 in the fourth, 11 in the fifth, 6 in the sixth, 4 in the seventeenth and 2 in the eighth. Twenty-seven had renal disease and 15 had diminished renal function, as evidenced by nitrogenous retention and diminished phenolsulfonphthalein excretion. Twelve patients were in a state of chronic debilitation from long-standing sepsis or neoplasm. There were 3 patients who had only one kidney. Thirteen were healthy individuals undergoing an elective operation.

The amount of evipal sodium used at first was 0.2 gm. per 4.5 kg. of body weight, dissolved in distilled water to make a 10 per cent solution. An adequate estimation of the proper dosage by weight alone is impossible, and a careful consideration of the general physical condition, age and size of the patient is imperative. Thus, we now give only two thirds or three quarters of the calculated dose to patients with anemia, cachexia, obesity, severe chronic infection or nitrogenous retention. The smallest total dose used was 1.4 gm., the largest 4.3 gm. and the average 3 gm. As with intravenous evipal, young, healthy individuals, particularly if apprehensive, require large doses for satisfactory results. In these cases evipal is probably less satisfactory than avertin. For elderly or debilitated patients or those with renal insufficiency, a small dose is adequate. The rather considerable individual variation in the effective dose, which is so important in the intravenous administration of the drug, is not quite so striking when it is given

rectally. However, it must constantly be borne in mind when a supplementary anesthetic is given.

The technic of administration is similar to that used for avertin. A thorough cleansing enema is given the night before operation. One hour before the evipal is to be administered the patient is given hypodermically 0.01 gm. of morphine sulfate and 0.05 gm. of ephedrine sulfate. Evipal frequently causes a sharp fall in blood pressure, which in our experience is prevented or mitigated by the use of ephedrine. Morphine appears to have a synergistic effect with evipal and causes a prompt and deeper anesthesia. The evipal solution is introduced into the rectum through a small catheter forty-five minutes before the operation is scheduled to begin. This may be done while the

patient is on the ward, and produces a state which varies from quiet analgesia to sound sleep. An excitement stage has failed to occur in 40 cases. Vigorous patients, particularly those in the second and third decades, and alcoholics are apparently awake when brought to the operating room, but a state of amnesia, always a great boon to the patient, is invariably produced, and even the more resistant patients appear drowsy. The induction of anesthesia with gas-oxygen is quite smooth, and it is frequently possible to obtain good relaxation with as low a ratio of nitrous oxide to oxygen as 1:3.

The effect of rectal evipal in the dose used is much more prolonged than that of the usual dose given intravenously. Thus the recovery period has varied from three to twelve hours after operation. The majority of patients are very drowsy, sleep comfortably through the night without medication and remember little or nothing until the day after operation. There has been a remarkable absence of excitement, headache and vomiting fol-

lowing operation. We have observed that these patients rest more quietly and are less troublesome to care for after operation than those who have received other forms of basal anesthesia. Cyanosis has not occurred as a postoperative complication. We have had no indications for the use of respiratory or cardiac stimulants. There have been no cases of postoperative shock, and the incidence of pulmonary complications in this small series has not been significant.

Table 1 presents a list of the operative procedures which have been done under rectal evipal as a basal anesthetic. Table 2 contains more detailed data on a representative group of cases. These were selected as being typical of the various groups of patients according to age, type of supplementary anesthesia and variations in the operative and postoperative courses. During operation there have been no striking changes in the pulse, respiration or blood pressure except in the cases in which ether was used as the supplementary anesthetic. In all 7 cases in which ether was used, difficulty was experienced in maintaining a sufficient depth of anesthesia without cyanosis, and in 6 there was a profound fall in the blood pressure. Consequently, ether was discontinued. Twenty-eight patients have received nitrous oxide and oxygen as a supplementary anesthetic. This combination of anesthetics has proved very satisfactory. As already noted, it frequently is possible to maintain good relaxation with a very low ratio of gas to oxygen. Of these 28 patients, 16 showed no fall in blood pressure and 5 showed only a slight fall. In 7 cases there was a fall of blood pressure of more than 30 mm of mercury. In no instance, however, was this alarming, as the general condition of the patient remained good and the lowering of the blood pressure proved to be only transitory. The

pulse rate tended to be elevated to a level which varied from ten to twenty beats per minute above the normal. No depression of the respiratory rate was noted in this series. In fact, there was frequently a slight elevation of the respiratory rate above the preoperative level for the individual patient.

Local anesthesia has been used in 4 cases, with excellent results. In 1 case no supplementary anesthetic was necessary. In these 5 cases no changes in the pulse, respiratory rate or blood pressure were noted. In patients beyond the sixth decade, local novocaine is the supplementary anesthetic of choice.

There have been no deaths which could be attributed to evipal. One patient in the series died, this was a case of extensive pyelonephritis with a perinephric abscess secondary to a blocked ureter. Death occurred one month after operation. It should be noted that although the patient was profoundly ill at the time of operation, he withstood the operative procedure under evipal and local anesthesia very well. As in our studies² with intravenous evipal, no changes in the liver or brain which could be attributed to evipal were found at autopsy.

SUMMARY

A clinical study of 40 cases in which evipal sodium was administered rectally as a basal anesthetic is presented. Ether was found unsatisfactory as a supplementary anesthetic, but gas-oxygen or local anesthesia proved highly successful. This type of basal anesthesia has a definite place in urologic surgery.

WHAT MASSACHUSETTS DOES FOR ITS MENTAL DEFECTIVES

NEIL A. DAYTON, M.D.*

BOSTON

BEFORE outlining the program of the Commonwealth in its state-school care of mental defectives, let us inform ourselves as to the meaning of the term Mental deficiency, or feeble-mindedness, is a condition of an arrested development of the normal structure of the brain, existing from birth or from an early age. Because of this arrested development the child shows an incomplete or imperfect development of the intelligence. This subnormal intelligence prevents the child from keeping pace with normal children of the same age. It keeps the adult from maintaining himself independently of supervision or external support.

It is important to understand the real meaning of mental deficiency. Many children and adults suffer from blindness, from deafness or from various crippling conditions. They lack the ability to see, to hear or to walk. These conditions are definite and tangible, we can see them with our own eyes and have no difficulty in understanding that the persons so afflicted are physically deficient. Now, other children and adults suffer from a similar lack or deficiency in certain nerve cells of their brains. These persons are mentally deficient. While the defect in brain structure is not visible to us, nevertheless mental defectives are to be considered crippled just as definitely as those with the more obvious physical disorders. Instead of being blind, deaf or unable to walk, they are unable to think as clearly or intelligently as persons without such brain defects†.

The various grades of mental deficiency depend upon the degree of the shortage of neurons, or "thinking" cells in the brain. In idiots we find a simple type of brain, with comparatively few neurons, and the mental age does not rise above three years. Those with a few more neurons are classified as imbeciles. The mental age of this group ranges between three and seven years. Those with brains containing a number of neurons approaching the normal are called morons. Here the mental age is higher, running between seven and eleven years. The borderline or dull normal groups are slightly higher in mental ages. Those with neurons closely packed together are normal

or superior in respect to intelligence. The measurements given apply to adults over sixteen years of age. For children we use an index, called the intelligence quotient (IQ). This is obtained by dividing the mental age by the actual physical age. Thus, a child of eight with a mental age of five years would have an intelligence quotient of 62, or 62 per cent of the normal for his particular physical age. He would be classified as a moron. We should exercise great caution, however, in being too greatly influenced by the intelligence quotient. Psychiatrists have learned, through experience, to place it last in order of importance when making a diagnosis of mental deficiency.

Is the state-school care of mental defectives something new, or has it been functioning for some time? Looking backward a bit we find that the House of Representatives, in 1846, appointed a committee, headed by Dr. Samuel J. Howe, to make a survey of idiots in Massachusetts**. Dr. Howe found 755 idiots throughout the State. When the General Court received Dr. Howe's recommendations, two years later, it generously appropriated \$2500 for the care of *ten* idiots for *one* year. We see that conservatism was a legislative trait even in those early days. In October, 1848, Dr. Howe received the first group of idiots who were to be cared for at the Perkins Institute for the Blind in Boston. Thus, there came into being the first school for the care of mental defectives in the United States. In October, 1887, Dr. Walter E. Fernald became superintendent, and the school moved to Waverley. The late Dr. Fernald's work in the development of educational and training facilities for backward children is well known throughout the country. In 1907 a second school was opened at Wrentham, under the late Dr. George L. Wallace, and in 1922, a third school at Belchertown, under Dr. George E. McPherson. At present, the three state schools are caring for about 5200 children. The capital investment of the Commonwealth in the three schools is about \$8,500,000, and the annual appropriations for maintenance total approximately \$1,800,000.

What is the general plan of attack of the Commonwealth for the care of its mental defectives? Training, training, and more training seem to be the answer to the condition known as mental deficiency. This training process is often slow and

†It is understood of course that other factors such as conduct and social reactions play important parts in the formal diagnosis. However the basic defect in brain structure remains the paramount issue.

I am indebted to Dr. Charles S. Woodall, assistant superintendent at the Walter E. Fernald State School for aid in the matter of historical data.

laborious, owing to the necessity of repeating the subject matter over and over again. The reception of new ideas or dexterity in new pursuits comes slowly to the mental defective. While he learns slowly he also learns well, and will retain much of his instruction to the last day of his life. Unhappily he will retain faulty teachings just as thoroughly. So we see how important is the matter of the early environment. Mental defectives do not have such a keen sense of judgment as normals in deciding between right and wrong. In emergencies they fall back on the teaching of their childhood. If it has been good, they make the right decisions, if faulty, they are apt to repeat the same errors again and again.

The training program of the state schools develops along three basic lines. The first is the establishment of a desirable set of habits. The second is educational in the sense of instruction in regular schoolwork. The third is occupational training to provide a means of self-support in later life. Every child sent to the schools is given an opportunity to advance in each of these fields so far as his characteristics will permit. Some, with limited endowments, never get beyond the establishing of good habit patterns. Others make some progress in the schoolwork, but can absorb only the rudiments of occupational training. Still others go through the entire course and return to the community as self-supporting citizens.

In the second step, that of education, we find the three state schools striving to equip the children with the classical three R's—reading, writing and arithmetic. The schools at Waverley, Wrentham and Belchertown have large school departments with from fifteen to twenty-five teachers. These school departments offer the children an education suited to their mental age. There is little point in teaching eighth grade arithmetic to the fourteen-year-old mental defective, who has the mentality of a nine-year-old. Obviously, third or fourth grade arithmetic is about his limit. The child is given the school material at a slowed rate, to match his own slowed powers of comprehension. Thus, it might take an entire school year to teach the child one half or one third of the regular grade material of that year. As soon as the teachers find that no further progress is being made, the academic schoolwork is terminated. This usually occurs at the age of sixteen years.

At this point the occupational training begins, with the goal of possible placement in the community held in the background. The length of time spent in the training period depends upon the boy or girl. Some are ready in two or three years. Others take longer. Girls are given individual instruction in classroom preparation of

food and then, for a period, they act as cooks in the main kitchen or in the various kitchens of the school. The domestic science teacher takes them in hand and instructs them in table service, and for another period they act as waitresses in one of the many dining rooms throughout the school. They are taught proper methods of management of a home, the purchase of food, cleaning methods, and so forth. Later, under supervision, they are made responsible for the work of a single ward or an employee's home. The occupational teachers instruct them in many kinds of sewing and dressmaking. The girls are instructed in the care of younger children in the school hospital and become quite expert in this work. Others learn to do clerical work or typing. While the training at first is general and calculated to equip the girl in all fields, it gradually works toward a development of the high points of the girl's potentialities. Then, when a call comes in for a certain type of service, the school is able to select a girl who has shown a special aptitude in that work.

The boys do shop work of various kinds—painting, printing, shoe repairing, and so forth. They may work in the various storerooms, with the baker, with the carpenter, with the electrician, in the garage, with the various construction gangs, in the powerhouse, in the horse barn, in the dairy barn, or on the farm itself. The boys are shifted from one division to another, to diversify the training. Actually, the farm turns out the largest number of boys as our calls are chiefly for boys with this training. However, if the boys show an aptitude for any other line of work, they are allowed to specialize in that activity. For example, we have had some boys leave the schools who were excellent cooks and others who were particularly good at housework.

The social workers are a *very* important part of the state-school training program. They take complete charge of the young woman or man who is to be placed at work in the community. Many persons know of the training programs and of the excellent workers turned out by the schools. Consequently, there is little difficulty in finding positions. As soon as the girls or boys are ready, positions are carefully selected which will suit their training, their capacities and their emotional make-ups. The social workers supervise these individuals very carefully and check all financial arrangements and payments. Starting at small wages, they receive raises at regular intervals as the value of their services increases. Positions are changed occasionally. After a period of supervision many cases are discharged completely and direct their own affairs from that point on.

In 1936, Belchertown, the smallest of our three

schools, had 68 boys and girls at work for wages in the community.* This group earned over \$9200 in wages, averaging about \$2.60 per week. Board, lodging, and in some instances clothing, were provided in addition to this salary. This is not a high wage, but when one stops to consider the thousands of normal persons who were on relief for that same year, we realize that these mental defectives did very well for themselves. The same 68 boys and girls had individual savings accounts totaling over \$8000, or an average of \$119 each. On these small incomes, they had actually saved money. The boys and girls take great pride in being on their own and self-supporting. When, in addition, they have achieved the distinction of having their own personal savings accounts, their pleasure knows no bounds. To these children the savings account is a tangible symbol of their success against overwhelming odds.

Quite incidentally, the placement in the community of this group of 68 persons relieved the

*I am indebted to Dr. George E. McPherson, superintendent of the Belchertown State School, for the financial data on graduates at work in the community. The Fernald and Wrentham state schools also maintain community placement and supervision plans with even larger numbers of cases at work for wages.

Commonwealth from the annual payment of over \$26,000 for their state school maintenance. Every year that these graduates remain in the community represents a clear saving to the Commonwealth of another \$26,000. Thus, the training programs of our state schools are not only restoring mental defectives to a productive life in the community but are being financially successful as well.

Many of these handicapped boys and girls have shown remarkable adjustments in the community, and have turned out to be excellent citizens. In 99 per cent of the cases the mental defective wants to be like other people, and to do the right thing. If given his chance through suitable training he will make a quiet, inoffensive citizen, capable of hard work and self-support. Massachusetts can well be proud of the work of Drs. Fernald and Wallace and their successors, Drs. Greene, Raymond and McPherson. All these workers have stressed the potentialities for good in mental defectives. All the latter are laboring unceasingly to carry on the efficient training programs which mean so much in the community adjustment of these handicapped individuals later in life.

PROGRESS IN HEMATOLOGY IN 1936

WILLIAM DAMESHEK, M.D.*

BOSTON

NO OUTSTANDING advance in the field of hematology took place during 1936. Despite this, the literature is so extensive that it has become difficult to keep abreast with even one aspect of it, such as purpura or pernicious anemia. One cannot fail but be impressed by the high caliber of the work which proceeds from so many clinics all over the world. Excellent hematologic work is being done not only in this country but in England, the Scandinavian countries, Italy and Russia. In England the literature is mainly concerned with clinical descriptions of the anemias, in the Scandinavian countries much investigation goes on regarding the pathogenesis and treatment of pernicious anemia, the Italians are concerned primarily with disorders of the spleen, particularly hemolytic anemia, and the Russians, in characteristic Soviet style, have rendered transfusions readily available to the masses.

This review represents only a sample of the world's literature. Less than two hundred articles are cited out of at least twenty times that number in the *Index Medicus*. The more important studies

are bone-marrow culture, bone-marrow biopsy, standardization of blood-cell counts, standardization of the tourniquet test, blood-transfusion methods, iron metabolism, isolation of liver-extract fractions, drug factor in purpura, lymph-node puncture, heterophile agglutination phenomenon, and the missing clotting factor in hemophilia.

BLOOD-FORMING ORGANS

Diagnostic Procedures By means of a complicated apparatus supplying an artificial "lung, kidney and circulation," Osgood and Muscovitz (*J A M A* 106:1888, 1936) reported the successful culture of human bone marrow in sufficient quantity for any hematologic or chemical procedure. The method was later simplified (Osgood and Brownlee, *J A M A* 107:123, 1936). These investigators outlined eighteen different problems which offered promise of solution by this method. Among them is one which has disturbed many people—the development of a practical test for the identification and standardization of the anti-pernicious-anemia principle. Other problems have to do with carrying on test-tube experiments relating to the various factors at fault

From the Medical Service and the Hematology Laboratory, Beth Israel Hospital, Boston.

Associate physician, Beth Israel Hospital.

in anemia, leukemia, agranulocytosis, and so forth. Whether the method, and the ambitious program outlined for it, will prove of value remains to be seen.

Many articles on biopsy of the sternal bone marrow continue to be written. Most of them are concerned with simple puncture of the marrow space with an abbreviated lumbar-puncture needle. Jaffé (*J A M A* 107 124, 1936) contributes a comprehensive review of the problem and cites the findings at biopsy in the various hematologic conditions. He concludes that the bone-marrow biopsy with a trephine as practiced by Custer and Dameshek is the method of choice for research and for systematic studies, since it permits sectioning of the marrow with preservation of the topographic relations of the cells, and also the preparation of smears and imprints. The accuracy of the simple puncture biopsy is open to much question, since the material obtained ("juice") is more often blood than marrow. (Cf. Schulzen, *Med Klin* 32 490, 1936). Despite the various defects of the puncture biopsy, its relative simplicity is of great advantage, especially when multiple punctures are contemplated. Furthermore, with increasing numbers of physicians who are interested in the findings in the marrow, the pathologic physiology of the various "blood dyscrasias" should become better appreciated.

Henning (*Med Klin* 32 542, 1936) reviews the various indications for the sternal bone-marrow biopsy. He mentions particularly his success in the diagnosis of multiple myeloma and of malignant metastasis to the bone marrow, and refers to the earlier work of Seyfarth and of Schilling in the diagnosis of malaria and kala-azar from the bone marrow. Rohr and Hegglin (*Deutsches Arch f klin Med* 129 61, 1936) were successful in finding tumor cells in sternal biopsy material from 10 of 12 cases showing tumor metastases to bone. Karavanov (*Sang* 10 562, 1936) contributes a modified technic for trephining the sternal marrow. Instead of making an incision through the skin and subcutaneous tissues, he pierces them by means of a special small trocar, through which the perforating trephine is introduced, after which marrow is removed by means of a small curette. This method seems to have some merit since with it one can obtain not only smears but pieces of tissue for sectioning.

One of the interesting investigative methods recently applied to study of the marrow cells has been that of the fluorescent microscopical technic. Porphyrin, the precursor of hemoglobin, develops a red fluorescence in the presence of ultraviolet light. Borst and Königsdorffer some years ago (1929) took advantage of this fact in studying the bone-marrow cells in various abnormal conditions,

with some particularly interesting results in pernicious anemia, in which they found that many of the megaloblastic cells contained porphyrin. They postulated from this that a gross abnormality in the "building stones" of the red cells existed in the disease. Seggel (*Folia haemat* 54 374, 1936) repeated these observations in both blood and bone-marrow smears, utilizing the same technic, and found inconstant and very slight fluorescence in the nucleated red cells of pernicious anemia, although fluorescence was noted in mature red cells and even in leukocytes. Müller-Neff (*Folia haemat* 56 18, 1936) extended these observations on "fluorescytes" and found that fluorescence was present only in young red cells (reticulocytes). This denoted that porphyrin was present during active hemoglobin formation and was therefore important in normal as well as in abnormal hemoglobin synthesis. Observations of this type, although admittedly very technical, deserve repetition because of the insight they may give to the physiology of blood formation. Another very interesting technic applied to bone-marrow cells is that of Kempner (*J Clin Investigation* 15 679, 1936), who studied, for the first time, the metabolism of human erythroblasts with the Warburg apparatus. He was fortunately able to obtain large numbers of nucleated red blood cells from the blood of a case of erythroblastic (Cooley's) anemia, and showed that the erythroblasts had a very high oxidative and fermentative metabolism, their respiration being approximately two hundred times greater than that of normal non-nucleated red blood cells. Indirectly these data indicate the relative lifelessness of the mature non-nucleated red blood cell, which is in reality not a cell but a bag containing a very active chemical—hemoglobin. The very high metabolic activity of these immature blood cells is not too surprising in view of the fact that the blood cells are the direct representatives in the adult of the primitive mesenchymal tissue. Studies of this type in bone-marrow tissue from various abnormal conditions should prove exceedingly interesting.

Wiseman, Doan and Erf (*J A M A* 106 609, 1936) bring out the very interesting reciprocal relation between the bone marrow on the one hand and lymphoid tissue on the other. By suitable animal experimentation and clinical observations, they demonstrate that with increased bone-marrow activity the lymphoid response becomes diminished, and vice versa. They postulate that there is a physiologic cellular equilibrium existing between lymphoid and myeloid tissue. Removal of a large amount of lymphoid tissue, as by splenectomy, will result in an increased activity of the marrow. Although this idea is attractive, it requires further experimental proof.

Methods In last year's review, the statement was made that "the day of the colorimeter seems gradually to be passing, and in its place is coming the era of the photometer and spectrophotometer, which utilize a given wave length of light for measurements of intensity of an unknown solution." This prediction is apparently becoming an actuality, since in many of the more advanced laboratories the colorimeter is being pushed into the limbo of forgotten instruments, owing to increasing realization of its relative inaccuracy. The "stabilized photoelectric colorimeter with light filters" of Evelyn (*J Biol Chem* 115 63, 1936) has proved its outstanding accuracy and ease of operation in many excellent laboratories. Evelyn's instrument disposes of the errors inherent in the previously used photoelectric colorimeters, and makes possible the rapid reading of concentrations of the various colored solutions used in colorimetry. It does away with the subjective element of the technician's eye, substituting for it the photoelectric cell, the fluctuations of which are transmitted to a galvanometer and depend entirely upon concentration of solution. The accuracy is within ± 2 per cent. To increase this accuracy, various types of color filters may be used for the different colorimetric procedures. Hemoglobin readings are very satisfactorily done with this apparatus.

Sedimentation rate continues to receive a large amount of attention. In common with various other investigators, Sasano, Ordway and Medlar (*Am J Clin Path* 6 432, 1936) studied the effect of various factors such as temperature, barometric pressure, manipulation and anticoagulants on the rate of erythrocyte sedimentation. They conclude that minimal and gentle handling of the blood is important, as well as the use of an isotonic anticoagulant such as 11 per cent sodium or potassium oxalate. Emphasis is placed on keeping the blood at body temperature, since this places the colloidal suspension in an environment approaching the normal. Wood (*Quart J Med* 5 1, 1936) contributes an important article on the sedimentation rate in heart disease. He found that congestive heart failure retarded the rate, and that increased rates were present in cases of active rheumatic heart disease, syphilitic aortitis and myocardial infarction. In the latter condition, the sedimentation rate was found to increase gradually to a maximum at about the end of the third week and to become slowly diminished as the infarct healed. The increase in rate is probably due to softening of the myocardium in the region of the thrombosis, whereas healing may be inferred when the rate diminishes. The somewhat accelerated rate with angina may be due to multiple tiny areas of myocardial softening. The test may be useful from

the prognostic and therapeutic standpoints, particularly in settling the vexing question of when to allow the patient to get out of bed. Since coronary disease occurs in the older age groups, it is important to know whether the sedimentation rate becomes disturbed in middle-aged and old persons. Miller (*J Lab & Clin Med* 21 1227, 1936) studied this problem and found that age had little effect, faster rates were accounted for by various abnormalities such as malignant disease, tuberculosis or cardiovascular disease. Reichel (*Med Klin* 32 1769, 1936) found the sedimentation rate increased in 90 per cent of cases with malignant tumors. Despite the nonspecific character of the test, it may thus be of value in distinguishing between the presence and absence of malignant disease.

Mean corpuscular volume, as determined by Win-trobe, is rapidly coming into greater prominence, as mentioned in previous reviews. Dunn and Sharpe (*Am J Clin Path* 6 497, 1936) have found that the necessary calculations are often a source of "perplexity and error," and propose a series of nomographic alignment charts to calculate the various indices. These charts are illustrated in the article, and may prove useful to those who do not enjoy the problems of simple arithmetic. Schartum-Hansen (*Folia haemat* 54 385, 1936) points out the very useful fact which we can confirm regarding the direct relation between the hematocrit (volume per cent of packed red cells) and the hemoglobin content. We have found that one of these observations may be used to check the other—or if we have one, the other may be roughly calculated. Thus, the approximate hematocrit may usually be reckoned by dividing the hemoglobin reading by two.

Much dissatisfaction exists with the fragility test, which as ordinarily done has many inaccuracies. Ponder has devoted many years of work to hemolysins, hemolytic systems and accurate methods, and the results have recently been assembled in a large volume (*The Mammalian Erythrocyte and the Properties of Haemolytic Systems*. Protoplasma-Monographien. Berlin: Gebrüder Borntraeger, 1934). The ordinary fragility test may be made more accurate by careful attention to volume of hypotonic salt solution, volume of the red cell suspension and degree of anemia (as measured by the hematocrit). The latter may be adjusted so that one always uses a fairly constant number of cells, even when there is present a marked anemia which will modify the results. These points are discussed by Daland and Worthley (*J Lab & Clin Med* 20 1122, 1935), who describe a modified method using hypotonic salt solution.

Wright and Lilienfeld (*Arch Int Med* 57 241, 1936) describe a *standardized tourniquet test*

which is useful in several conditions, particularly in hemorrhagic disease and in scurvy. Instead of recording a tourniquet test as negative or positive, as is usually done, these authors record the number of petechiae which appear and can be seen by the naked eye in a circle of 2.5 cm diameter, 4 cm below the crease of the elbow. The tourniquet used is the cuff of a blood-pressure machine which is inflated to a point midway between systolic and diastolic pressure and maintained for fifteen minutes. In this way the results obtained can be recorded and their variations noted from day to day.

Although not directly related to hematology, some mention should be made of *gastroscopy*, which is being used more and more for direct examination of the gastric mucosa. The relation of disorders of the stomach to anemia has become so well known that investigators have naturally become interested in it. Thus Jones, Benedict and Hampton (*Am J M Sc* 190:596, 1935) have studied the gastric mucosa in various cases of anemia. An excellent summary article of the subject of gastroscopy is contributed by Schloss (*Internat Clin* 4:1, 1936).

CERTAIN CHEMICAL CONSTITUENTS

Normal and abnormal *porphyrin metabolism* is discussed by Dobriner (*J Biol Chem* 113:1, 1936) and Watson (*J Clin Investigation* 15:327, 1936). These investigators are among the very few in this country working in this difficult but important field. In 3 cases of lead poisoning Watson was able to isolate a porphyrin established as coproporphyrin III. The anemia and stippling found so commonly in lead poisoning are probably related to disturbances in the porphyrin metabolism. Bence, Lendvai and Székely (*Ztschr f klin Med* 130:299, 1936) studied the *copper content* of the blood in anemia, and concluded that since this element was increased when there was evidence of rapid regeneration of the red cells, copper probably had a definite action on red cell growth.

BLOOD CELLS

General Kato (*J Lab & Clin Med* 20:1243, 1935) has performed a worthy service for both the clinician and the technician in putting together in simple tabular and pictorial form the origin, development and interrelation of the formed elements of the blood. The resultant schema is easy to follow, and has proved a boon to technicians. Despite the simplicity of the colored lithograph and tables, accuracy is not sacrificed. The monophyletic schema of blood-cell formation is utilized, all cells being derived from the primitive mesenchymal cell, this in turn produces "myeloblasts,"

which give rise to various types of erythroblastic and leukocytic cells. In a paper by Hansen-Prüss (*Am J Clin Path* 6:423, 1936) the blood cells are studied by the infrequently used technic of dark-field illumination. The author claims that "the method avoids the involved and somewhat unreliable technical factors encountered in the use of the supravital dyes and in staining of fixed smears." Apparently, malarial parasites are well brought out with this method, which may prove to have a very limited value. Rosahn and Casey (*Am J M Sc* 192:456, 1936) in a very careful study compared the quantitative variations in the "hemacytologic constitution" of healthy men and rabbits. The blood formula of both these mammalian types differed widely from individual to individual, indicating that there might be an inherent or constitutional variability. Thus a blood-cell formula normal for one individual may in fact be abnormal for another. This is of particular importance, the reviewer has found, in estimating whether leukopenia or leukocytosis is present in a given case. The normals of different individuals vary so widely that one should not immediately conclude that a count of 5000 white blood cells constitutes leukopenia, or that of 12,000 leukocytosis. This also holds true for the differential percentages of white cells.

Red Blood Cells Leverton and Roberts (*J A M A* 106:1459, 1936) studied the daily variations in hemoglobin and red cell counts with particular reference to the menstrual cycle in 4 normal college women. This work, which was done as part of a complete study on the iron metabolism, brought out clearly the occurrence of daily variations in both hemoglobin and red cells which were apparently unaffected by the menstrual process. The writers point to the difficulty involved in making generalizations from single observations, when rather marked daily variations are normally present. The reviewer can confirm this statement, especially when such abnormal states as pernicious anemia are followed from week to week, variations here are even more difficult to interpret. The factors of technical error, I find, are insufficiently recognized by the profession at large, which often accepts at face value the printed reports from a technician or technical laboratory.

Myerson, Loman and Dameshek (*Am J M Sc* 192:560, 1936), in studying the pharmacologic effects of benzedrine in human subjects, found that this drug when injected caused a marked increase of the erythrocyte and leukocyte counts, probably through a "squeezing" action which resulted from vasoconstriction of such organs as the spleen and marrow. Levy-Simpson and Cadness (*J Pharmacol & Exper Therap* 56:389, 1936) performed similar experiments in guinea

pigs with a closely related drug, ephedrine, and demonstrated (by splenectomy) that the spleen is not essential for the rise in red cells, leukocytes and platelets, but that ephedrine probably causes extrusion of these cells into the circulation from storage and hematopoietic centers, including the bone marrow

Langendorff and Reisner (*Folia haemat* 55 88, 1936) studied the normal reticulocyte count in man and concluded that the figures usually given—0.5 to 1 per cent—are much too low, their average figure being 11 to 17 per cent (!) The daily variations present are dependent upon the "normal rhythm of the biologic milieu" Although these conclusions are interesting, it seems strange that so many workers in widely separated laboratories have reported normal values which are under 1 per cent As for the existence of daily variations, these are doubtless correct, but their clinical value is questionable Jacobsthal (*Klin Wchnschr* 15 942, 1936) makes the interesting observation that in a new malarial infection it is the reticulocytes which are chiefly infected, not the mature red cells Ninety to 93 per cent of the infected cells are reticulocytes, this being the case, anemia more readily develops since the younger cells are being destroyed

Grunke and Diesing (*Klin Wchnschr* 15 1190 1936) found an increase in the reticulocyte percentage during the spring Forkner, Zia and Teng (*Chinese M J* 50 1191, 1936) found that the red cells exhibited rhythmic movements when studied supravivally (molecular streaming?)

BLOOD TRANSFUSION

Much is being written nowadays about blood transfusion. The Russians have their institutes of transfusion in which are kept on hand large quantities of blood of the various types, ready for immediate use As is well known, the Russians have pioneered in the use of cadaver blood, which as yet has failed to find favor in this country The chief contribution of the Russian school is, however, that of storage of the blood for a period up to two weeks, possibly longer Beyond that period, the plasma is utilized for other purposes The French now have their central clearing stations where blood of the various types is kept on hand for the different hospitals ready for instant use In Chicago, at the Cook County Hospital, a "blood bank" has been set up, which performs the functions of collecting all available blood and of dispensing it on call (What a relief this must be to long-suffering interns and technicians who spend many hours of work in typing and cross-matching many hundreds of donors!) In all fairly large hospitals, some effort might well be made

to conserve blood which is frequently wasted and to have it readily available for transfusion purposes The blood from patients with hypertension, right-sided heart failure, and polycythemia might well be utilized Large quantities of polycythemic blood are routinely used at the Beth Israel Hospital (Boston) for transfusion Pickering (*Clin Sc* 2 185, 1936) has found that blood from patients with hypertension is similar to normal blood in its content of pressor and depressor substances and is thus useful for transfusion Bock (*New Eng J Med* 215 421, 1936) summarizes the safe and sane attitude in transfusion and lists indications He finds that transfusion is done too often as a gesture, or as a "filler" to take up time during anxious hours when "something must be done" Frequently more harm than good results, particularly when reactions develop The latter are all too common, they may be due not only to incorrect typing but to other disturbances resulting in chills and fever Simple compatibility tests are not enough, in addition, both patient and donor should be typed Except in very rare instances this will avoid the tragic experiences which all too frequently occur Occasionally, intragroup reactions will occur, as described by Culbertson and Ratcliffe (*Am J M Sc* 192 471, 1936) In the case cited, both the recipient and donor were of Group O (Type IV, Moss), but a very severe renal reaction occurred, almost resulting fatally Hanging-drop compatibility tests were repeatedly negative, but by the test-tube method and the centrifuge-test method (Wiener *Blood Groups and Blood Transfusion* Springfield, Illinois Charles C Thomas, 1935) it was found that the patient's serum agglutinated the donor's cells and also that of 22 or 23 other Group O (Type IV) donors Except in two instances the hanging-drop method failed to show agglutination Because of this and another experience, Culbertson and Ratcliffe now utilize the following routine procedures in choosing a blood donor (1) grouping the patient with test serums, (2) cross-matching recipient's serum with donor's cells and donor's serum with recipient's cells, by both hanging-drop and centrifuge-test methods, and (3) Kline test of the donor They state that, although this routine may sound cumbersome, it has not slowed up the laboratory service Except in extreme emergencies one can never be too careful, even at the expense of a little more lost time. The ordinary transfusion reactions are not, however, dependent upon blood-group phenomena but are due to nonspecific protein reactions, which are probably caused in great part by technical errors Filatov, Blinov and Depp (*Arch f klin Chir* 184 647, 1936) recommend the following precautions for reducing the incidence of these reactions (1) careful cleansing

of the apparatus for blood transfusion, (2) prevention of blood clotting, (3) observance of painstaking asepsis, (4) maintenance of proper temperature of the blood and (5) using distilled water free from any impurity for the chemical solutions

Many new modifications in transfusion are being made. The use of preserved blood, referred to above, is being rapidly taken up all over the world. All the authors testify to its quick availability in emergencies and to its safety, particularly if the blood has been preserved at a constant very low temperature (1 to 4°C), and if it is used within a week. In the treatment of severe hemorrhage, as from peptic ulcer, Marriott, Kekwick and Wood (*Brit M J* 2 115, 1936) have successfully utilized continuous intravenous blood transfusion. This has proved of far greater value than the continuous infusion of large quantities of saline and dextrose solutions, and has often led to dramatic improvement in physical status and hemoglobin percentage. Citrated blood is given at the rate of from 90 to 150 cc an hour for from twelve to forty-eight hours. Fonio (*Schweiz med Wchnschr* 66 337, 1936) suggests the use of fractional blood transfusion—red cells or platelets, as needed in the individual case. The erythrocytes can be used for anemia, the platelets in thrombocytopenia and the plasma in fibrinopenia or for increasing the blood proteins. Fonio has had no direct experience with this method, which, however, appears to be of some practical value. The reviewer has given platelet transfusions in thrombocytopenia, but great care must be taken in the handling of platelets so as to prevent the formation of thrombi. Hedenius (*Acta med Scandinav* 89 263, 1936) suggests the novel method of heparinizing the donor, with consequent ability to transfuse the patient at leisure and without worry about coagulation. For once the donor is considered in an article by Merklen, Israël and Apfell (*Presse Méd* 44 1941, 1936), who studied the effect of frequent venesections in professional donors. The hemoglobin concentration was reduced in several and there was a tendency to leukopenia and neutropenia. Regeneration after venesection is fastest in the erythrocytes, slightly less rapid in the hemoglobin and still slower in the white cells.

WHITE BLOOD CELLS

Intelligent observation of changes in the numbers and characters of the blood cells will often prove of great benefit in the study of many infectious diseases. Particularly is this true of conditions in which long-standing infection is present. A very stimulating contribution along these lines is presented in a symposium on "Progress in Tuberculosis" in which are featured articles by Doan

(*Ohio State M J* 31 921, 1935) and Wiseman (*Ibid*, p 925). Liberation of the active chemical materials which make up the tubercle bacillus affects the tissues and, among other things, is reflected in alternations of quantitative relation and qualitative characteristics of the blood cells. Sabin, with her studies on the differential picture produced by the various fractions of the tubercle bacillus, has been able to state categorically that a certain fraction of the carbohydrate will produce a neutrophilic response, and so forth. On the basis of these and other observations, Wiseman lists the following hematologic changes and their possible significance:

- Red blood count
 - High—obstruction in oxygenation.
 - Low—secondary infection predominating.
- Hemoglobin
 - Low—measure of degree of toxemia.
 - Low— inadequacy of iron reserve.
- Neutrophils
 - Qualitative changes measure toxemia.
 - Quantitative changes measure caseation.
- Monocytes
 - Measure degree of proliferation of lesions.
- Lymphocytes
 - Qualitative changes measure resistance.
 - Quantitative changes measure healing.
- Sedimentation index
 - Measure of toxemia.

The word "intelligent" at the beginning of this section is used advisedly. It presupposes a thorough knowledge of the various factors which might cause changes in the blood picture, it signifies that inaccuracies of methods, variations in counts and variations in cellular relations from moment to moment must be well understood (Cf Medlar *Arch Int Med* 57 367, 1936). In other words, it is not possible to draw sweeping conclusions from routinely done differential counts. If the analyst is also the technician and in addition has a wide knowledge of the disease in question, his conclusions will be of great value. Mechanical systems for deriving the prognosis of a certain disease from mathematical formulas and simplified slide rules, are much to be deplored.

Medlar (*Arch Int Med* 57 367, 1936) contributes an important paper on "rest" and "activity" levels of leukocytes in health and disease, in which are brought out many of the thoughts noted above. The frequent normal variations in leukocyte counts even within a period of half an hour should make one wary of too exact interpretation. Too much attention, Medlar states, has been centered on the total leukocyte count, which is often of much less significance than the differential picture. Despite these variations in count, however, no serious interference in the interpretation of leukocyte counts should occur.

Mendell, Meranze and Meranze (*Am J M Sc* 192 316, 1936) continue their studies on the cytoplasmic and nuclear changes in neutrophils occurring in severe infectious states. The reviewer has pointed out many times that in pyogenic infections certain changes occur in the cytoplasm of the polymorphonuclear cells, which in general constitute an index of the severity of the infectious process. A slight degree of "toxic" change results in irregularity in staining and spacing of the cytoplasmic granules, a moderate degree results in more striking manifestations of the same type, a marked degree results in vacuolization of the cytoplasm. Mendell, Meranze and Meranze found that degenerative cytoplasmic changes occurred earlier than nuclear changes (band forms, non-filamentous forms) and were more valuable for diagnostic and prognostic interpretation than the Schilling hemogram. Of course, this depends upon the point of view, and to a great extent in the particular problem at hand, knowledge of and careful attention to both types of phenomena are of greater value than study of a single factor. Fleming (*Quart J Med* 5 105, 1936) brings out the fact that the extent and type of leukocytosis in lobar pneumonia depends to a large extent upon the type of organism present. Thus, with Type-I infection, a leukocytosis of over 20,000 is characteristic, while with Type-II infections, a leukocytosis of less than 20,000 is usually found. If the age of the patient, the duration of the illness and the bacterial type of the pneumonic infection are known, the prognostic value of the leukocyte count may be considerable. Lobar pneumonia is probably not one disease entity, but each type infection is a disease in itself.

Carey and Litzenberg (*Ann Int Med* 10 25, 1936) studied the leukocyte count in pregnancy and found that leukocytosis was a common feature. Alieff and Reekers (*Klin Wchnschr* 15 1522, 1936) describe some further cases of Pelger's syndrome. In 1930, Pelger described 2 cases which presented a constant and marked "shift to the left" of the polymorphonuclear cells, with the presence in the blood of large numbers of immature granulocytes, usually of the "young" type. Other cases were soon described, and Huet in 1932 found 2 cases in one family. Alieff and Reekers, when they found a typical case, studied the family (which was a large one) and discovered 13 cases in 40 individuals from three generations. The cause of this hereditary disorder of the bone-marrow white cells is not known, like sickling of the red cells, it may be a congenital abnormality of growth.

Many articles are still being written extolling one type of diagnostic or prognostic test above all others. The conservative view to take, it would

seem, is that tests like the leukocyte count, differential count, sedimentation rate, and so forth, are of value only as aids in evaluating symptoms. In tuberculosis, for example, Miller (*Nebraska M J* 21 140, 1936) wisely writes that the ideas regarding prognosis, degree of activity and efficacy of therapy cannot be obtained simply by taking one test as a criterion, but by consideration of a series of successive, correlated studies of the Schilling test, blood sedimentation rate and monocyte-lymphocyte ratio. These procedures may be of aid in demonstrating the presence or absence of pathologic activity. Rinkel (*J Allergy* 7 356, 1936) describes his experience with the "leukopenic index" which was devised by Vaughan for the study of "food allergy." Theoretically, if an individual is hypersensitive to a given food, his bone marrow will react with the production of a leukopenia, if he is not, a leukocytosis results. Rinkel confirms Vaughan's observations regarding the misleading character of clinical impressions and skin tests in food allergy. Since studies of this type have not as yet been well controlled, the reviewer is inclined to be very skeptical regarding them.

PLATELETS

Too often the platelet count is neglected in hematologic studies. This is mainly because of the relative difficulty of technic and the lack of a standardized method. In our own laboratory, satisfactory results have been obtained since 1930 with the use of an "indirect" method in which the fresh blood comes in contact with sodium citrate and brilliant cresyl blue (Dameshek *Arch Int Med* 50 579, 1932). Olef (*J Lab & Clin Med* 20 416, 1935) uses a somewhat more difficult but also "indirect" method. The normal platelet counts with both of these methods range between 400,000 and 800,000 per cubic millimeter. A reliable index of bone-marrow activity may be obtained from study of (1) the total leukocyte count, (2) the polymorphonuclear percentage, (3) the reticulocyte count and (4) the platelet count. Reduction in blood platelets is often the first sign of serious disease of the bone marrow and may antedate all the other signs above enumerated. Olef (*Arch Int Med* 57 1163, 1936) has also studied the differential platelet count and has divided the platelets into four groups depending upon their size. The smaller platelets are much more active functionally than the larger types (giant platelets are dwarves in function). Increased numbers of large platelets are seen in various functional abnormalities of the marrow. Arneith, whose encyclopedic treatises on the various qualitative changes in the leukocytes during infectious disease were so complicated that they were neglected for many years, now appears to be doing the same thing for the

"qualitative thrombocyte picture" (Lymphatic leukemia *Folia Haemat* 56 49, 1936 Tetanus *Deutsches Arch f klin Med* 179 51, 1936 Acute miliary tuberculosis *Klin Wchnschr* 15 964, 1936) Arneth continually stresses that the qualitative platelet reaction, like that of the erythrocytes or leukocytes, is a true biologic reaction which should give a particularly good insight into various pathologic conditions Zondek and Kaatz (*Brit M J* 2 387, 1936) conclude that the platelet count is considerably influenced by the thyroid and the thyrotropic hormones They were able to increase the count in normal individuals by administration of these substances Olef (*J Lab & Clin Med* 22 128, 1936) showed that large platelets are more mature than small ones and disintegrate more rapidly than younger ones In infectious and post-operative states the platelets are increased in number and exhibit an increased fragility which might be of significance in the pathogenesis of spontaneous venous thrombosis

ANEMIA

As emphasized by the reviewer on many occasions, anemia is the expression of some bodily change which because of one or several factors has resulted in reduction of the hemoglobin concentration or in the number of circulating red cells Anemia is never primary, and is always secondary to some cause or causes, whether or not they are readily discernible The emphasis is now placed upon the cell size rather than upon the primary or secondary character of the anemia Knowledge of the cell size may be obtained (1) by simple inspection of the stained blood smear, (2) by actual measurement of the diameter of at least one hundred red cells and (3) by determination of the hematocrit red-cell relation (mean corpuscular volume) Knowledge of the cell size immediately gives one an idea not only of possible etiology but also of the therapeutic possibilities If the red cells are small (microcytic), a deficiency of iron is present, and if hemorrhage, infection, malignancy, and so forth can be ruled out, we may be dealing with chronic hypochromic anemia, and so iron should be of great value, with large cells, some form of liver deficiency is probably present and liver extract should be beneficial, if on the other hand, the red cells tend to be of normal size, one should suspect a destructive process of the marrow, amenable neither to liver nor to iron therapy

Again, one should always remember that anemia, although a striking manifestation, is merely one symptom of many bodily changes, thus, in an iron-deficiency state the symptoms of glossitis, gray hair, flabby skin and flattened fingernails are just as important manifestations as the anemia itself

These symptoms are not the manifestations of anemia, rather the anemia and the other symptoms are manifestations of a more general deficiency of iron

IRON-DEFICIENCY STATES (CHRONIC HYPOCHROMIC ANEMIA)

Etiology Most interesting has been the decline of chlorosis and the rise of chronic ("primary") hypochromic anemia Chlorosis, apparently* so common in the Victorian Era, has by now almost disappeared Both conditions, characterized by a chronic deficiency of iron, are associated either with the beginning or the end of the menstrual cycle Although chlorosis is rarely described, it is not entirely defunct, as Patek and Heath (*J A M A* 106 1463, 1936) bring out These observers described 4 cases and demonstrated in them various factors which were probably responsible for the state of chronic iron deficiency a poor, capricious appetite, a hereditary factor in the presence of an anemic mother, hypochlorhydria or achlorhydria, and menorrhagia They emphasize that adolescent girls require much more iron than the adult male, chiefly because of the great increase in growth which takes place, together with the onset of regular loss of blood at the menstrual cycle When a girl is already at a disadvantage because of poor heredity, a poor diet or a poorly functioning gastrointestinal tract, the added demands for iron by the growing organism probably are just sufficient to bring about the condition which has been called chlorosis

The problem of iron metabolism is being pursued vigorously in various clinics Whipple and Robscheit-Robbins (*Am J M Sc* 191 11, 1936) in their group of anemic dogs found that iron given intravenously to an anemic although otherwise normal dog, will be practically completely utilized and will be returned quantitatively as newly formed hemoglobin Iron given by mouth does not result in such proportional hemoglobin production Even the optimal dosage of iron will result in only about 35 per cent utilization of the iron given These investigators could find no difference in action between the ferrous and ferric forms of this element Widdowson and McCance (*J Hyg* 36 13, 1936) assessed the total and "available" iron intakes of 63 men and 63 women of the English middle class The mean daily intake of iron for the men was 168 mg, for the women 114 mg Thirty per cent of the women took less than 10 mg of iron daily Lower hemoglobin concentrations in women may be due to insufficient

*The word apparently is used advisedly Inspection of the records of a number of cases of chlorosis indicates that various conditions with anemia were uniformly called by this name. The lack of recorded blood counts in most of the case reports makes the diagnosis even more uncertain

iron intake and to loss of iron with the menstrual cycle

Kellogg, Mettler and Purvance (*J Clin Investigation* 15 241, 1936) attempted to determine the relation between diet and digestion in hemoglobin production of experimental animals. When anemia was induced in dogs by bleeding, the feeding of beef resulted in a marked rise in hemoglobin output. When the stomach was removed, however, hemoglobin regeneration was greatly reduced. From these experiments it would appear that, once an anemia is induced and the iron reserves depleted, this state will continue if the normal gastric secretion is lacking. Mogensen (*Folia haemat* 56 206, 1936) discusses the anemia of gastric carcinoma and concludes that its main causes are undernutrition and failure of the antianemic activity of the stomach.

Heath (*M Clin North America* 19 1685, 1936) again emphasizes the importance of normal intestinal absorption for the prevention of the anemic state. With malabsorption, as in chronic diarrhea from whatever cause, iron-deficiency states readily develop even though the iron content of the food is entirely adequate. In this regard, Greppi and Deleonardi (*Clin Med Ital* 67 349, 1936) describe a typical case of "achylic hypochromic anemia" in the course of intestinal amebiasis and lamblasis in an adult.

Gray and Wintrobe (*Am J Obst & Gynec* 31 3, 1936) studied 40 cases of hypochromic microcytic anemia of obscure origin and found many gynecologic abnormalities, including uterine myomas, endometrial hyperplasia and unexplained menorrhagia. Multiple pregnancies were common. They concluded that the anemia in these cases was the result of faulty alimentary function, defective diet and excessive demands for hemoglobin (as with menorrhagia). Haden (*J A M A* 106 261, 1936) brings out the important fact that many conditions are characterized by multiple rather than by single nutritional deficiencies, whether in iron, vitamin-B complex, antipernicious anemia substance, and so forth. The deficiency may be due to a deficient intake of the specific food factors for normal needs, an insufficient supply for abnormal needs as in pregnancy, a defect in absorption or a disturbance in utilization. Bethell (*J A M A* 107 564, 1936) criticizes the view of Strauss and Castle that the temporary reduction of gastric acidity, with resultant impairment of gastric digestion, is an important causative factor in the development of the anemia of pregnancy, and concludes that this anemia is due either to a pre-existing iron depletion or an inadequate intake of protein of high biologic value during gestation. Snyder (*J Kansas M Soc* 37 143, 1936) suggests

that since in the majority of patients with idiopathic hypochromic anemia there is no history of dietary deficiency, the condition is probably caused by some difficulty in the absorption or utilization of iron by the body. The achlorhydria so commonly present, and indicative of a gastric defect is probably the central point.

In the presence of a chronic iron deficiency the following symptoms and signs of varying degrees of severity will usually develop: graying of the hair with a peculiar lack-luster appearance, a wrinkled flabby skin, sores at the corners of the mouth (perleche), a reddened and later an atrophied tongue, atrophied buccal and other mucous membranes, dysphagia and at times esophageal webs, achlorhydria, flattened, brittle fingernails and finally diminution in the amount of circulating hemoglobin, with a resultant lowering of the color index and microcytosis and achromia of the red blood cells.

Treatment Treatment with almost any preparation of inorganic iron, provided it is given in sufficient dosage, will almost invariably result in prompt amelioration of symptoms and improvement of the physical signs and the blood picture. Witts (*Lancet* 1 1, 1936) contributes an important article on the therapeutic action of iron in which are discussed the hematopoietic area of the alimentary tract, the normal and abnormal iron requirement, the potentiation and antagonization of iron and the dosage of different preparations of iron. Witts discusses the variability in the individual reaction to the same dose of an iron salt, an average effective dose is that which produces an average increase of over 1 per cent of hemoglobin a day in a sufficiently large number of patients with achlorhydria and anemia. Injection of iron is hazardous because the therapeutic dose is so close to the toxic dose. The therapeutic activity of preparations given by mouth is in direct proportion to their solubility and to the ease with which they yield free ions of ferrous iron. The soluble ferrous salts are the most effective, from 20 to 100 per cent of such salts are utilized, depending upon the dose given. (The reviewer uses ferrous sulfate ["exsiccated"] in a dosage of 12 to 15 gr daily.)

With regard to "potentiation" of iron, Pituk (*Arch Int Med* 57 73, 1936) describes the results of iron and chlorophyll products, administered separately and combined, and orally and parenterally, to patients with chronic hypochromic anemia. By using the "double reticulocyte response" method, he found that an enhanced effect occurred with the use of preparations of chlorophyll. The study suggests that the body can use preformed pyrrol substances in the regeneration of hemoglobin, and should encourage the liberal use of greenstuffs and protein foods in the diet.

Hughes and Latner (*J Physiol* 86 388, 1936) state, however, that chlorophyll may act as a physiologic stimulant of the bone marrow without being directly concerned in the chemical regeneration of the porphyrin groupings

PERNICIOUS ANEMIA

Etiology Pernicious anemia may be considered as a symptom complex which is the end result of a long-continued deficiency of liver extract within the body. This deficiency may be brought about in many ways: an inadequate diet, an impaired gastric function, disordered intestinal absorption, depletion of storage reservoirs in the liver or a combination of these. The end results of liver deficiency are seen characteristically in the hair, the tongue, the gastric mucosa, the central nervous system and the bone marrow. The megaloblastic changes in the bone marrow are sooner or later reflected in the peripheral blood, which shows an anemia with large red cells, leukopenia and a reduction in platelets. Because of the striking character of the blood picture, the disease has for many years been considered as primarily an anemia. In reality, the anemia present is only *one* of the many manifestations of liver-extract deficiency, which in turn is brought about by many diverse causes. The anemia of the disease called pernicious anemia is no more a "primary" condition than is the anemia of a case of "secondary" anemia. In the first instance, the red cells are large (because of the megaloblastic character of the liver-deficient bone marrow), whereas in the second instance the cells are small and hypochromic.

Although many etiologic factors may be cited as contributing to the development of the symptom complex, the outstanding feature is usually the striking abnormality in the gastric juice, which Castle demonstrated was due to the absence of an enzyme (intrinsic substance) active in the digestion of protein- and vitamin-B-containing foods (extrinsic substance). Without this enzyme, these foods are insufficiently digested, the bone marrow (and presumably other organs such as the central nervous system) do not receive sufficient material for normal activity, and so the well-known changes result.

Goldhamer (*Am J M Sc* 191 405 1936) found that the intrinsic substance was present in cases of pernicious anemia but in greatly reduced amounts, chiefly because the gastric juice was itself greatly reduced in quantity. The degree of reduction in intrinsic substance varied from patient to patient. This work is important because it explains the development of pernicious anemia in some patients following a more or less prolonged dietary deficiency, and conversely the good response to treatment in certain instances following

a good diet or the feeding of large amounts of vitamin-B complex.

Greenspon (*J A M A* 106 266, 1936) reanalyzed Castle's fundamental experiments on the basis of another explanation which had suggested itself to him. He found that gastric extract (ventriculin) was without effect in the presence of pepsin, but that depepsinized ventriculin was highly effective. He suspected that the extrinsic factor (meat) of Castle's feeding experiments acted simply as an agent in the adsorption of pepsin, this rendered the enzyme inactive and allowed the intrinsic substance to act unimpeded. In other words, the extrinsic-intrinsic interaction of Castle was subject to a different interpretation than that given by its author. Greenspon concluded that it is not necessary to postulate the presence of an extrinsic factor in pernicious anemia, but that the disease was inherently caused by a defect in intrinsic substance.

This work of Greenspon's, which caused a mild sensation when reported in the *Journal of the American Medical Association*, where it received extensive editorial comment, has been uniformly rejected by a number of different investigators. Thus Ungley (*Lancet* 1 1232, 1936) found that completely depepsinized gastric juice and pepsin-free extracts of pylorus mucosa had little or no hematopoietic effect when given orally, unless the interaction with a source of extrinsic factor (for example, autolyzed yeast) was allowed. They also found that the interaction of intrinsic and extrinsic factors did not require incubation outside the body, implying therefore that Greenspon's experiments might have been misinterpreted because that observer failed to allow completely for such a contingency. Hanes, Hansen-Prüss and Edwards (*J A M A* 106 2058, 1936) obtained completely negative results by feeding depepsinized gastric juice to 5 patients with pernicious anemia; they also suggested that Greenspon's results might have been due to the presence of extrinsic factor either in the stomach of the patient or in the gastric juice of the donor. Castle and Ham (*J A M A* 107 1456, 1936) repeated all Greenspon's experiments, reanalyzed Castle's previous results and conducted some new experiments. All this work tended to show that Greenspon had not adequately controlled the factor of food administration, and that an interaction between the intrinsic and extrinsic substances must have occurred within the body. Castle concedes, however, that pepsin does have some inhibitory effect, especially when gastric juice digestion mixtures are allowed to stand for some time. Other facts not brought out by Greenspon are that the gastric juice in pernicious anemia is completely devoid of pepsin, that gastric juice

alone has no effect and that ventriculin and gastric mucosa are not suitable for experimentation, since they contain (as Castle has shown) not only intrinsic but extrinsic substances which by their interaction provide material that stimulates bone marrow

Vladov, Bagdasarov, Dulcin and Bondarenko (*Acta med Scandinav* 88 295 1936) in experimental gastric resection in dogs found that the anemia which developed varied in type depending upon some constitutional factor as yet undetermined. Resections of different portions of the stomach indicated that Castle's factor was produced both in the fundus and in the pylorus and was probably a ferment, not a hormone. Bence (*Ztschr f klin Med* 130 275, 1936) found that following total gastrectomy in dogs a microcytic, hypochromic anemia at first developed, which gradually became modified in one or two years to a megalocytic, hyperchromic anemia, with all the other features of pernicious anemia in the blood and bone marrow. Cheney (*Am J Digest Dis & Nutrition* 3 341, 1936) concludes, on the basis of treating patients with pernicious anemia with a mixture of liver extract and duodenal mucosa, that Castle's gastric factor is present in the duodenum in a concentration equal to or greater than that in the stomach. This is in line with the work of Meulengracht (*Acta Med Scandinav* 85 79, 1935), who showed that the "pyloric gland organ" (presumably producing intrinsic factor) might be present as far down as the middle of the small bowel. The presence of active tissue in the duodenum would explain the failure of all cases of human total gastrectomy to develop pernicious anemia. Cheney prefers to consider pernicious anemia as due to a combined gastroduodenal defect. It is probably better, however, to consider that the disease is the end result of several different types of abnormalities which in many cases are combined.

Berger and Grill (*Folia haemat* 54 398, 1936) state that in the present state of our knowledge pernicious anemia is brought about by (1) occult causes, accounting for most of the cases, (2) parasites, (3) infections such as lues, (4) impairment of hormones as in pregnancy and old age and (5) gastrointestinal changes. Chemical causes are exceedingly rare, the authors describe a case which is said to have been caused by long-continued carbon-monoxide absorption from a badly functioning stove. The relations between the stove, the carbon-monoxide poisoning and the development of the disease are, it must be admitted, well worked out, although nothing definite is proved. The writers hazard the conjecture that continued absorption of carbon monoxide by the blood stream resulted in changes in the gastric mucosa, with diminution

in the production of both hydrochloric acid and the various enzymes

Pathology and Symptoms Jones (*Proc Soc Exper Biol & Med* 34 694, 1936) in a preliminary paper reports studies of biopsied pernicious-anemia bone marrow during relapse, and makes the point that the entire marrow is involved ("panmyelopathy"). Not only is the red cell series affected with proliferation of megaloblastic cells, but abnormal leukocytic and megakaryocytic growth takes place. Similar studies, together with a correlation of the blood and bone-marrow picture, both in relapse and following induced remission by liver extract, are described by Dameshek and Valentine (*Arch Path* 23 159, 1937). In this paper a sharp line of demarcation is drawn between the liver-deficient type of erythropoiesis (megaloblastic) and the normal and iron-deficient type (normoblastic). The "total" character of the bone-marrow involvement is also emphasized. Hoffmann (*Klin Wchnschr* 15 598, 1936) in studying the white blood-cell picture in the disease concludes that liver extract acts not only on the red cells but on the leukocytes as well. If the platelets had been studied, the same conclusion would have been drawn regarding this blood element. In other words, liver-extract deficiency brings about changes in the red cells, white cells, platelets, hair, tongue, gastrointestinal mucosa and central nervous system. Great variation in the localization of the deficiency is present. This is well brought out in the central-nervous-system manifestations. Turrelles and Vázquez (*Semana Méd* 2 1583, 1936) discuss this factor, and describe a case with marked involvement of the posterior columns of the spinal cord in the cervical region. Cohen (*Lancet* 2 1202, 1936) describes 2 cases in which optic atrophy preceded by a considerable period the clinical manifestations of pernicious anemia and were quickly benefited by treatment with liver extract. The reviewer has also observed 2 such cases.

Treatment Aside from etiologic considerations, most of the articles about pernicious anemia are concerned with therapy. A completely satisfactory method for the assay of various antianemic substances has not yet been discovered, despite some interesting observations regarding the reticulocyte responses which occur in guinea pigs. In last year's review, mention was made of Jacobson's method of assaying the potency of liver extract in guinea pigs. This method has since been criticized by Goodman, Geiger and Klumpp (*J Klin Investigation* 15 435, 1936), who on the basis of a large and well-controlled series of experiments conclude "The normal adult guinea

pig shows considerable and unpredictable spontaneous fluctuations in reticulocyte levels. These variations are of such a nature as to render this normal animal unsuitable for assaying the potency of materials effective in pernicious anemia. Unfortunately, the human assay of liver extract must still remain the only completely satisfactory one at present, although this too is beset with many difficulties.

Gänsslen (*Med Klin* 32 533, 1936) reports on the treatment of pernicious anemia with minimal doses of a parenteral liver extract, Campolon (Winthrop). This investigator, who prepared the first commercial extract for injection, found that he could obtain strikingly effective results, often maximal, following the injection of only from 2 to 6 cc of liver extract (derived from 20 to 60 gm) and given in one dose. In one case 2 cc of this relatively dilute extract given once resulted in an excellent reticulocyte response, which was followed without further treatment by a rise in erythrocyte count from 1.8 to 4.1 million in four weeks. He makes the important observation that the daily injection of parenteral extract with the subsequent careful follow-up of the reticulocyte count (as recommended by Dameshek and Castle and now prescribed by the Council on Pharmacy and Chemistry of the American Medical Association) may be misleading, since the reticulocyte reactions obtained might all have been caused by the first injection given. (This is true if maximal injections are given, but not when suboptimal doses are administered.) Be this as it may, all observers are agreed that the maintenance dose varies greatly from patient to patient, and must be determined in each case by a careful follow-up study.

Subbarow, Jacobson and Fiske (*New Eng J Med* 214 194, 1936, and *J Am Chem Soc* 58 2234, 1936) continue their important studies on the isolation of the active "pernicious-anemia principle" in liver. A number of different fractions have already been isolated, and it is probable that some of these fractions exert a primary or initiating therapeutic action, whereas others augment and complete the reaction. In the last paper by these writers fractions H and I are described, together with their clinical activity in cases of pernicious anemia (no mention is made of assaying the extracts by the use of guinea pigs). A somewhat similar fraction has been isolated by the Scandinavian investigators, Laland and Klem (*Acta med Scandinav* 88 620, 1936), and has been clinically tested by Strandell, Poulsson and Schartum-Hansen (*Acta med Scandinav* 88 624, 1936). A "good antianemic effect" was obtained by use of an aqueous solution containing 0.7 mg (1) of this fraction.

The number of extracts of liver for clinical use is becoming bewildering. One often wonders why the pharmaceutical houses go to such pains to produce, concentrate, refine and advertise their extracts in view of the relative scarcity of cases of pernicious anemia. It is probably because injections of liver extract are given almost indiscriminately for any case presenting anemia, whether this is hemorrhagic, nephritic or leukemic in origin. In reality liver extract is of value only in liver-extract deficiency states (pernicious anemia and related conditions). Its use following hemorrhage in chronic iron deficiency and in other conditions is wasteful of the patient's money and of no value whatever to him. In pernicious anemia, the type of extract to use and its dosage must depend on the patient and the preference of the physician. Almost any injectable extract now on the market will produce a satisfactory reticulocyte and erythrocyte response provided it is given in sufficient quantity. It is true that some extracts far exceed others in potency, but with present-day concentration large amounts of active principle can be given in relatively small total amounts of solution. In cases of pernicious anemia with neurologic symptoms larger and more frequent doses of parenteral extract must be given to obtain successful results. Hyland and Farquharson (*Arch Neurol & Psych* 36 1166, 1936) recommend, in addition to liver extract, keeping the patient in bed during the early months of treatment. Reactions to liver extract sometimes occur, and these may be coped with by desensitization procedures or by changing to an extract from a different animal. Most extracts are made from pig liver. Campolon (Winthrop) is derived from beef liver and Chappell's liver extract from horse liver.

MACROCYTIC ANEMIA NOT PERNICIOUS ANEMIA

An increase in the average red-cell diameter and in the mean corpuscular volume is not pathognomonic of pernicious anemia. Aside from related conditions (caused by a gross dietary gastrointestinal disturbance) which are in reality as much entitled to the designation "pernicious anemia" as the so called primary disease itself, there are a number of conditions associated with macrocytosis of the red cells. Much interest has developed in recent years in the macrocytic anemia of hepatic disease and its possible relation to pernicious anemia.

Wintrobe (*Arch Int Med* 57 289, 1936) has been one of the chief advocates of the essentially identical nature of the macrocytic anemia of liver disease and pernicious anemia. He studied 132 cases of severe hepatic disease, including examples of cirrhosis, malignant disease and various miscellaneous disorders. No anemia was present in

30 cases, macrocytic anemia was present in 43, normocytic anemia in 40 and microcytic anemia in 19. The mean red-cell count in the group of cases with macrocytic anemia was 3.48 million and the mean corpuscular volume 103 cubic microns. In 4 cases of macrocytic anemia there was some response to treatment with liver extract. Foci of extramedullary hematopoiesis were found in the spleens of several cases at postmortem examination. Wintrobe concluded that the macrocytic anemia of hepatic disease was morphologically similar to that of pernicious anemia, if not identical with it. The evidence at present, Wintrobe states, suggests that when damage to the liver is so extensive that storage is interfered with, and when it has been of sufficient duration to permit exhaustion of the hematopoietic principle already present, macrocytic anemia develops. Only a few studies of the bone marrow were made in these cases, and these failed to reveal anything but a slight hyperplasia in some of them.

There can be no question that the anemia in these cases of hepatic disease was caused, at least in part, by disease of the liver, but very little convincing evidence that the anemia is identical with that of pernicious anemia is presented. Too much emphasis is placed, it seems to the reviewer, on minor changes in the mean corpuscular volume. Anything above 94 cubic microns is considered macrocytic, this may be strictly true, but many a case presenting anemia shows a mean corpuscular volume up to 105 cubic microns, without definite macrocytosis being present, as seen in the blood smear. The macrocytic anemia, if present, in certain of these cases might have been caused by red-cell abnormalities which have nothing in common with the fundamental megaloblastic abnormality of true pernicious anemia. The liver is undoubtedly a storage reservoir, but it is probably not the only one in the body, with loss of hepatic function the body may still get liver substance through the diet, and may call upon stores in the kidneys and other organs.

On the experimental side, Higgins and Stasney (*Folia haemat* 54 129, 1936) produced cirrhosis of the liver in rats by causing them to inhale the fumes of carbon tetrachloride. A marked anemia of the macrocytic variety developed, although hypochromasia was, paradoxically enough, also present. These authors felt that there was definite correlation between the extent of the hepatic cirrhosis, the degree of the anemia and the extent of the macrocytosis. Goldhamer (*Cyclopedia of Medicine* [Rev Vol.] P 137 Philadelphia F A Davis Co., 1936) cites some previous experimental work in which an extract prepared from a case of severe alcoholic cirrhosis of the liver with a very low red-

cell count failed to produce a response in a case of pernicious anemia when it was given parenterally. Goldhamer states that five factors may produce a microcytic anemia: deficiency of extrinsic factor, deficiency of intrinsic factor, deficient absorption from the bowel, deficient storage in the liver, and lack of utilization by the body tissues. In the present state of our knowledge it is not possible to accept definitely the concept of Wintrobe and others that the macrocytic anemia of hepatic disease is identical with that of pernicious anemia. What has come out of these studies is the emphasis on the role of the liver as a storage reservoir and the fact that large red cells may occur with hepatic disease.

The fifth of Goldhamer's factors, impaired utilization, has recently been the subject of an interesting article by Israels and Wilkinson (*Quart J Med* 5 69, 1936). These authors describe a group of 4 cases in which, although the blood picture and most of the clinical features were quite typical of pernicious anemia, there was free hydrochloric acid in the gastric juice and a failure of response to specific antianemic therapy. Despite numerous transfusions, the cases all ended fatally. Because the bone marrow was typically megaloblastic, because there was no response to liver therapy and because the liver itself when assayed later showed adequate antianemic substance, the authors concluded that there must be a failure of utilization ("achrestia") of liver substance from the normal stores in the body and from substances injected into the body. They consider that although these cases are rare, they comprise a distinct group which are labeled achrestic anemia. Whether or not the speculation that there is impaired utilization is correct, the hypothesis is an intriguing one. Confirmation is needed before it can be accepted.

Napier (*Lancet* 2 679, 1936) describes 11 cases of tropical macrocytic anemia probably caused in great part by vitamin-B deficiency, since they responded to treatment with an autolyzed yeast preparation without added liver. Hanes and McBryde (*Arch Int Med* 58 1, 1936) discuss a syndrome which has acquired many different names during its curious history: nontropical sprue, idiopathic steatorrhea, Gee's disease and celiac disease. The "sprue syndrome" is probably a better name, it has no relation to tropical residence, and is probably a deficiency syndrome closely related to tropical sprue. Macrocytic anemia is usually present, and is remarkably benefited by adequate liver therapy. Macrocytic anemia may also occur in a variety of intestinal conditions, as pointed out by Butt and Watkins (*Ann Int Med* 10 222, 1936), particularly in disorders of the terminal ileum. Liver extract may be of no value in these

cases, which are benefited by surgical procedures Cheney (*Folia haemat* 56 28, 1936) describes a "megalocytic hypochromic" anemia in pancreatic disease

HEMOLYTIC ANEMIAS

It is customary to group under this title not only congenital and acquired hemolytic jaundice, but erythroblastic (Cooley's) anemia and sickle-cell anemia, although it is recognized that the hemolytic factor in the latter two conditions may be slight

Most observers have accepted Haden's views that the essential abnormality in congenital hemolytic jaundice is that of the red cell, which is abnormally small, round and thick ("spherocyte") and thus more susceptible to hemolysis. There is, however, something to be said for the opposing view which holds that the abnormality lies in an unusually active reticuloendothelial system (spleen, and so forth), which destroys more red cells than is normally the case. Along these lines are the observations of Levi and Bairati (*Am J M Sc* 190 610, 1935), who demonstrated that after splenectomy in 1 case of congenital hemolytic jaundice the red cells became larger and their fragility somewhat diminished. This indicates that the bone marrow was capable of normal erythrocyte production but that the spleen was primarily at fault. If the reader is particularly interested in this phase of the problem, two Italian articles are of great interest, those by Levi (*Haematologica* 16 1001, 1935) and by Dominici (*Ibid* 17 185, 1936). The latter article gives a thorough discussion of the two theories involved, either or both of which may be correct.

A most unusual report is that of Scott (*Lancet* 2 872, 1935), who reports the sudden development of acute hemoclastic crises in 4 children of one family. Although the crises of sudden anemia with jaundice occurred in sequence within a period of three weeks, no common cause could be demonstrated. All the children showed unusually labile ("accordion-like") splenic enlargement. The development of hemoclastic crises in cases of congenital hemolytic icterus, although rare, is an important phenomenon from the therapeutic standpoint, for unless energetic treatment, particularly transfusions, is resorted to the patient may die of anemia. Certain of these cases may require "emergency" splenectomies, as pointed out by Doan, Curtis and Wiseman (*J A M A* 105 1567, 1935).

Many kinds of hemolytic anemia in addition to the well-defined one of congenital hemolytic jaundice are being reported, with the result that the literature on this subject is chaotic. This is particularly true of the acute types of hemolytic

anemias, which many authors indiscriminately classify under Lederer's anemia. The latter disorder, described some years ago by Max Lederer, is thought to be infectious in origin and is characterized by rapidly progressive hemolytic anemia, dramatically cured by transfusion. Lovibond (*Lancet* 2 1395, 1935), among others, reports a case of macrocytic hemolytic anemia in which transfusions were of no value and which was responding to splenectomy until the patient died of sepsis. Several similar cases have been reported, and the reviewer has recently seen 3 more in which dramatic recovery followed splenectomy. Is this Lederer's anemia, or another type? Owing to the fact that no sharp dividing lines have been drawn between the various types of acute hemolytic anemia, which although superficially similar may be as apart as the poles, cases are being reported under many different headings, and doubtless a number of rare cases are not recognized with resultant fatal exitus. To miss an opportunity for splenectomy in a suitable case may be a fatal error.

In a fascinating article, Hamburger and Bernstein (*Am J M Sc* 192 310, 1936) describe an uncommon type of chronic hemolytic anemia associated with paroxysmal hemoglobinuria. There were anemia, reticulocytosis and perpetual hemoglobinemia, the urine always contained urobilin and hemosiderin. Transfusions and splenectomy did more harm than good. Waugh (*Am J M Sc* 191 160, 1936) reports 2 cases of severe hemolytic anemia in carcinomatosis, with extensive involvement of bone and bone marrow. These cases are chiefly of interest from the diagnostic point of view, since cases of metastatic malignancy and of Hodgkin's disease may occasionally present themselves as hemolytic anemia.

"SPLENIC ANEMIA"

Klemperer (*Am J Clin Path* 6 99, 1936), in a very important paper on the pathologic anatomy of splenomegaly, calls attention to the fact that gross enlargement of the spleen does not necessarily indicate primary involvement of that organ, since enlargement occurs in a host of varied conditions, and the spleen is an organ in which large numbers of reticuloendothelial cells are concentrated. Klemperer believes that such vague diagnoses as Banti's disease and splenogenous anemias should be abolished. It is at present impossible to classify the various disorders associated with splenic enlargement on etiologic or physiologic grounds, so that a "morphologic-pathogenetic" classification might be best. According to this method, splenomegaly may be classified as (1) inflammatory (bacterial endocarditis, malaria, syphilis), (2) infiltrative (Gaucher's disease, and so forth), (3) hyperplastic (polycythemia, purpura, and so forth), (4)

neoplasm, (5) cysts and (6) chronic disturbances of blood circulation, as in obstruction of the portal or splenic veins and in cirrhosis of the liver. In the last-named condition, the spleen was enlarged in 79 per cent of the cases. Klemperer very carefully outlines Banti's original conception of a "new" disease characterized by splenomegaly and later by cirrhosis of the liver, and concludes that neither the clinical picture nor the histologic splenic lesions are specific, but may occur in many other conditions. He makes this cogent observation: "The alleged favorable results of splenectomy at this [the early] stage cannot be used as a basis for diagnosis of this disease, because there is no evidence to prove that the progress of the disease was actually arrested."

Rousselot (*J A M A* 107 1788, 1936) studied 31 cases presenting splenomegaly, anemia and leukopenia, often with intestinal hemorrhages and sometimes with ascites. These comprised a heterogeneous group consisting of 9 cases of Laennec's cirrhosis, 2 of unclassified cirrhosis, 2 of schistosomiasis infestation, 2 of thrombosis of the splenic vein, 1 of cavernomatous transformation of the portal vein and 15 in which the obstructive factor was not demonstrated. The feature stressed by this author is the hypertension in the portal circulation, which is caused by an "obstructive" factor, either demonstrable or speculative. Splenic venous-pressure determinations in a few cases gave much higher readings than in the peripheral venous circulation. The results of splenectomy are presented. This major procedure should be avoided when hematemesis has already occurred, and also when there is marked involvement of the liver. The best results of operation occurred where an obstructive factor in the portal circulation could not be demonstrated, in 10 of 15 of these cases, the patients were alive and well from four to ten years after operation. Concomitant with clinical improvement, there was usually a rise in the various blood values.

MISCELLANEOUS TYPES OF ANEMIA

The anemia in pregnancy was studied by Boycott (*Lancet* 1 1165, 1936). Cases with normal and with subnormal color indices were equally divided. The cases with normal color index might be caused by a simple dilution of red cells dependent upon an increased plasma volume, which is irregularly present in pregnancy. Those with a low color index belong to the iron-deficiency group and respond readily to iron. Bethell (*J A M A* 107 564, 1936) contributes an important article on the hematologic changes in pregnancy in which he criticizes the view of Strauss (*Ann Int Med* 9 38, 1935) that the anemia of pregnancy can be

simply classified in two types: an iron-deficient (hypochromic) and a liver-deficient (pernicious). Bethell contends that there are cases which do not respond to iron and which are not macrocytic, but normocytic. These cases are usually associated with a low-serum-albumin level and respond to a high-protein diet. The reviewer can confirm these data of Bethell's in a few cases. On the other hand, it is important to recognize the macrocytic (pernicious) type of anemia in pregnancy in its incipency, because these cases may go rapidly downhill, and are exceedingly refractory to even very large doses of parenteral liver extract.

Kato (*J Pediat* 9 433, 1936) and Astwood (*Canad M A J* 34 501, 1936) report cases of aplastic anemia in which the etiologic factor was not discernible, although in Kato's case the child was fond of inhaling the odors of kerosene and gasoline. Astwood's case is distinguished by its complete recovery, which was apparently consummated by eight transfusions with such supplemental drugs as liver extract, iron, yeast, raw bone marrow, epinephrine and ephedrine. The great majority of the idiopathic cases are fatal, those with a readily discernible etiology (arsenic, arsphenamine, benzol, and so forth) stand a fairly good chance for recovery provided that supportive measures, chiefly transfusions of blood, are persisted in. Astwood rightly criticizes the concept of complete bone-marrow aplasia as necessary to the diagnosis of aplastic anemia. Small islands of hematopoietic tissue may be present and may act as centers of regeneration, thus justifying continued transfusions.

POLYCYTHEMIA

The etiology of the "true" or "primary" type of polycythemia is still unsolved, although most observers suspect that an anovemic condition of the marrow is present. An attempt to bolster this conception is the work of Reznikoff and his collaborators, already referred to in last year's review, this indicated that the blood vessels of the marrow showed evidence of disease. From the experimental standpoint, it is difficult if not impossible to interfere with the circulation of such a widely scattered organ as the marrow, and from the clinical standpoint it must be admitted that only an occasional marrow in polycythemia will show the well-defined changes pictured by Reznikoff and his collaborators. The theory that the disease is caused by a hypersecretion of "Addison" and therefore the antithesis of pernicious anemia (Morris and collaborators) has been discredited. About a quarter of the reviewer's cases of polycythemia present achlorhydria, and in most the free acid is present in normal or some-

what diminished quantity. Peptic (gastric or duodenal) ulcer is present not infrequently—in 4 of 25 cases observed at the Beth Israel Hospital. Kraemer and Asher (*Am J M Sc* 191 234, 1936) report 2 cases in which duodenal ulcer and erythremia were coexistent, and refer to the report of Wilbur and Ochsner (*Ann Int Med* 8 1667, 1935), who found that 8 per cent of the 143 cases of polycythemia at the Mayo Clinic presented peptic ulcer. Kraemer and Asher attempted to reduce the red-cell count in one of the above 2 cases by daily gastric lavage. The patient's ulcer symptoms were relieved but his red-cell count showed no change and the therapy was discontinued. The most important etiologic factor seems to be racial, as observed by Reznikoff. Twenty-four of our 25 patients were Jewish, most of them of Russian or Polish origin. Statistics from most large clinics show that polycythemic patients are usually Jewish, although this group may number only about 10 per cent of the hospital population.

Certain cases of polycythemia with known etiology are of interest, particularly those in which pulmonary arteriosclerosis is present (Ayerza's disease). Darley and Doan (*Am J M Sc* 191 633, 1936) report a well-studied case of this sort in which there was extensive pulmonary arteriolar sclerosis with dilatation of the pulmonary artery and right ventricular hypertrophy. The red cell count was about 7.5 million, and the total blood volume was increased.

In our experience, the diagnosis of polycythemia is frequently missed, and the patient may go about for several years with his ailment labeled as heart disease, vascular disease of the extremities, migraine, and so forth. The diagnosis should be considered in all individuals with a plethoric appearance, particularly if they are of Jewish origin. A hemoglobin test by the commonly used Tallqvist method is of no value, so that a red cell count should be done in suspected instances. It might be well to perform this count in all cases of vascular disease of the extremities, the occasional discovery of the disease discovered in this manner more than compensates for the many normal counts.

Treatment of the condition is still unsettled, some observers continuing to recommend phenylhydrazine, others x-ray therapy, and others frequent venesections. Phenylhydrazine is a difficult drug to control, requiring much co-operation by the patient. X-ray therapy is expensive, drastic and in the reviewer's experience almost always unsuccessful. Hunter (*New Eng J Med* 214 1123, 1936) reports excellent results with spray radium in 2 cases. We have been unable to affect the disease at all in 3 cases, in spite of using small

dosage in spray form as recommended by Hunter. Our chief reliance in recent years has been on the production of an iron-deficiency state. This consists in the removal of 500 cc of blood twice weekly for three or four weeks at the beginning of treatment, followed by the induction of a diet deficient in iron. With this method the patient's symptoms completely clear up, the hemoglobin is kept between 75 and 85 per cent of normal and the erythrocyte count between 50 and 70 million. The hematocrit and hemoglobin tests are the important factors to watch, and these generally remain at normal or slightly low levels for from six to nine months, following which another small series of venesections is given. (The venesected blood may be used for transfusion purposes.) The method has proved very successful in 10 successive patients, and is entirely free of the dangers of phenylhydrazine toxicity and drastic roentgen ray therapy.

DISORDERS OF THE WHITE BLOOD CELLS

Glandular Fever. Unfortunately, last year's statement in this review that glandular fever is one of the most commonly overlooked diseases in general practice does not require modification at this time. Davidsohn (*J A M A* 108 289, 1937) points out the many conditions with which the disease is often confused. Grippe is of course the most obvious, the patient has a sore throat and slight fever, and the lymphadenopathy is not suspected. Since abdominal pain is present in some 20 per cent of the cases, owing to involvement of mesenteric lymph nodes, the diagnosis of appendicitis may be made and the patient operated on. Furthermore, since the leukocyte count is commonly elevated and a differential count is rarely done, it is readily seen how the error may be made. Some of the cases of so-called mesenteric adenitis are in reality examples of the more generalized disorder, infectious mononucleosis. The reviewer has seen cases of so-called catarrhal jaundice, purpura or streptococcal sore throat prove to be typical examples of the disease, once the lymphadenopathy and the blood picture were recognized. More care in the palpation of lymph nodes in their respective situations would result in the presumptive clinical diagnosis of the disease, the final diagnosis then being made from examination of the blood smear and by performance of the heterophile agglutination test.

The changes in the lymph nodes have not been studied very extensively, although the pathology has recently been put on a firmer basis by the publication of Downey and Stasney (*Folia haemat* 54 417, 1936). These observers point out that although occasionally the node resembles the picture of leukemia, there is never the complete loss of structure

seen in advanced cases of leukemia and there is no invasion of the capsule. The reticulum is generally hyperplastic, with transformation of some of the cells to lymphocytes. The blood picture is the end result of the extreme hyperplasia found in the lymph nodes, and indicates "a reaction that is more or less leukemoid in nature to an infective, toxic, lymphotropic agent."

The nature of the infectious agent has not yet been elucidated. What relation it has to the positive sheep-cell agglutination test has yet to be worked out. Studies continue to be made on this most interesting diagnostic test, which so far has been shown to be positive only in serum sickness and infectious mononucleosis. The work of several groups of investigators indicates that the agglutinins of serum sickness are of a different type than those of glandular fever, and may be absorbed by appropriate substances. Beer (*J Clin Investigation* 15 591, 1936) contributes an important article in which stress is placed on the differential testing of suspected blood serum with the cells from horses, goats and cows, as well as sheep. Methods are outlined for differentiating cases of serum sickness and infectious mononucleosis.

Although it is comforting to obtain a positive agglutination test, the diagnosis should readily be made from the blood picture which shows marked lymphocytosis, extreme variability in the types of lymphocytes with all sorts of large, abnormally shaped and abnormally stained cells, no anemia and no reduction in blood platelets. The latter three criteria are of importance in distinguishing the condition from acute leukemia which shows monotony of leukocytic picture, anemia and reduction in blood platelets. In many mild cases the heterophile test is negative. N. Rosenthal, in a personal communication, states that the test is positive in only about 30 per cent of his cases. Complications are rare. High fever may at times be present, this is usually in association with secondary involvement of nodes with Vincent's infection. In these cases, the intravenous injection of neoarsphenamine in small doses frequently results in a dramatic drop in temperature and reduction in size of the glands. Otherwise, no treatment is necessary and all patients make an uneventful recovery.

AGRAULOCYTOSIS

During the past year, enough data have been accumulated regarding this disease to allow us to write a summary of most of its important aspects.

Etiology. When the disease was first described (1922), and for about ten years thereafter, very little was known about its cause. Infection, a pe-

culiar metabolic disturbance, some endocrine abnormality, and allergy were all implicated. Beginning in 1931, articles began to be written implicating various drugs, principally amidopyrine (Kracke, Madison and Squier). The etiologic relation between amidopyrine and the disease became quite evident from a large series of articles from American and various European sources. Other drugs, notably dinitrophenol, have been implicated. Cases following the use of a drug related to amidopyrine (Novaldin) have recently been reported by Benjamin and Biederman (*J A M A* 107 493, 1936), following cinchophen by Shapiro and Lehman (*Am J M Sc* 192 705, 1936), and following quinine by others. It was naturally brought out that amidopyrine and the various sedative mixtures associated with amidopyrine (Allonal, Peralga, and so forth), although they were being used in enormous amounts, rarely brought about the disease. The possibility of allergy was suggested by several authors. In a study of the various mechanisms involved, Dameshek and Colmes (*J Clin Investigation* 15 85, 1936) subjected 4 patients, who had recovered from the disease, to intensive study. All four when given from 5 to 50 gr (0.3 to 3.2 gm) of amidopyrine by mouth developed severe headaches and malaise, then striking reduction in white cells and granulocytes, and finally necrotic lesions of the mouth, tongue and throat. Patch tests, scratch tests and intradermal tests with amidopyrine solution were all negative, but when the drug was "aged" with blood serum for several days and the resultant mixture injected intradermally, striking skin reactions occurred, the controls being negative. This indicated that a definite allergic condition was present and that there might be a drug-protein linkage such as had been demonstrated for other chemicals by Landsteiner. Not only did skin reactions occur, but 2 of the 3 patients tested promptly developed severe agranulocytosis, although only approximately a few milligrams of amidopyrine had been injected. This definitely and conclusively showed the extreme hypersensitivity, idiosyncrasy or allergy of certain individuals to the drug amidopyrine, and indirectly explained why the great majority of individuals taking it had failed to develop the disease. It was now possible to piece together the physiologic and pathological principles involved.

Pathologic Histology. After preliminary reports by many writers, which were often actually contradictory, a number of reports on the pathologic lesions of the bone marrow were published by different investigators, all of whom agreed on essential particulars. Fitz-Hugh and Krumbhaar coined the term "maturation arrest" to indicate the con-

dition of the marrow at the height of the disease a marrow crowded with primitive white cells which were apparently prevented from maturing or unable to mature to normal polymorphonuclear cells. This report was soon confirmed by Jaffe, by Custer and by Parker, Darling and Jackson. All these authors emphasized that although the peripheral blood was barren of polymorphonuclears, the marrow was crowded with immature leukocytes. Rohr (*Folia haemat* 55 305, 1936) in a comprehensive investigation studied the bone marrow during life and correlated it with the blood picture. He used the method of bone-marrow puncture, and was thus able to make frequent examination during the course of the disease. He also produced agranulocytosis experimentally in several patients by giving them amidopyrine, and observed the bone marrow before and after administration. "Maturation arrest" of the bone-marrow granulocytes developed, and Rohr concluded that this was an anaphylactic reaction, with the bone marrow acting as the "shock organ." Plum (*Ugeskr f Laeger* 98 919, 1936) did the same experiment with 3 patients, and concluded that administration of amidopyrine by mouth to amidopyrine-hypersensitive persons produces an extraordinary severe and protracted inhibitory effect on granulocytogenesis. The reviewer has shown from unpublished data that giving amidopyrine in large doses to a group of normal individuals will induce a reduction in granulocytes and in white cells in about 25 per cent, when the drug is discontinued, a marked increase in leukocytes and in granulocytes usually occurs ("release phenomenon"). All these pieces of evidence indicate quite clearly (1) that certain individuals have developed a hypersensitivity to amidopyrine, (2) that the hypersensitivity is manifested by severe shock to the bone marrow, with particular reference to the production and maturation of the bone-marrow white cells, (3) that, in the presence of maturation arrest of granulocytes, the peripheral blood becomes depleted of polymorphonuclear cells, (4) that after this has gone on for a few days, the effects of agranulocytosis become clinically manifest, with high fever, malaise, prostration and necrotic lesions of the mucous membranes, and (5) that in the absence of granulocytes, secondary sepsis is easily possible, because of the presence normally within the mouth and other parts of the body of bacteria, and so septicemia may develop.

Diagnosis The diagnosis of the typical case is relatively simple. Although marked prostration is present, there is relatively little to show for it beyond the presence of lesions of the gums, throat or other mucous membranes. If petechiae are

present and anemia is marked, it is likely that agranulocytosis is not present, but rather some disease entity in which, although the granulocytes are very much reduced, the bone marrow as a whole is affected and there are anemia and thrombocytopenia as well. This combination of anemia, leukopenia and thrombocytopenia may be caused by aplastic anemia (benzol, arsenic, gold, and so forth), by carcinoma or lymphosarcoma metastasizing widely into the bone marrow, or by leukemia or generalized Hodgkin's disease, which has overrun the marrow. The differential diagnosis of these conditions is best made by bone marrow biopsy, as the reviewer has repeatedly pointed out (Dameshek *Am J M Sc* 190 617, 1935). Agranulocytosis itself is usually associated with only slight if any reduction in the red cells and without reduction in the platelets.

Treatment Although there is a good deal of disagreement among observers, the only consistent therapeutic results which have been obtained have followed the use of certain nucleic-acid derivatives. Chief among these are a mixture of pentose nucleotides (Pentnucleotide) given intramuscularly in 10-cc doses several times daily, and adenine sulfate, given intravenously in 1- to 2-gm doses, dissolved in 50 to 100 cc of normal salt solution. The reviewer prefers the latter medication, because it seems more rapidly effective and its use is not attended by reactions. Within from forty-eight to sixty hours immature granulocytes usually appear in the circulation, to be followed later by an increase in the total leukocyte count. If the diagnosis is delayed, therapy will be ineffective. Jackson and Parker found that 67 per cent of 103 patients recovered, whereas prior to the introduction of this method of therapy the rate of recovery was only from 10 to 25 per cent.

LEUKOSES (LEUKEMIA)

Since the time of Virchow, who in 1847 first described a case of "weisses Blut," the only progress that has been made in this disease has been in the fields of classification and description. Most authorities are agreed upon the malignant neoplastic character of the disease, although an occasional observer discusses its possible infectious or metabolic character.

Wiseman (*Ann Int Med* 9 1303, 1936) in a lengthy and important paper discusses the possible metabolic character of certain cases of lymphatic leukemia from a clinical analysis of various types of lymphoid hyperplasia. After a discussion of normal lymphopoiesis, he takes up the history of the development of our concepts of the lymphoid hyperplasias and divides them into four main types: lymphatic leukemia, lymphatic pseudoleukemia, leukosarcoma and aleukocytemic

(aleukemic) lymphatic leukemia Lymphatic pseudoleukemia is the same pathologically as lymphatic leukemia except that the cells do not get out into the blood stream (are screened out?) Leukosarcoma represents a sarcomatous disorder of lymphoid tissue with the formation of pathologic lymphocytes which get out into the blood stream and give the picture of leukemia Aleukocytemic (aleukemic) lymphatic leukemia is a disorder in which the cells are lost from the blood stream into the tissue spaces and tend to overgrow the blood-forming organs Wiseman concludes that there are two types of lymphatic leukemia a metabolic form which is probably more common and in which the cells are normal in type but do not mature as they normally should, and a neoplastic form which tends to overrun tissues in typically malignant form The concepts of Wiseman are based on much study and observation and although in many respects unorthodox they are worthy of careful consideration

In last year's review, the experimental observations of Furth were discussed These concerned the transmission of leukemia from rat to rat with the production of local neoplasms, leukemia and aleukemic states at will, according to the method of injection utilized Not infrequently one sees clinical sarcoma (either myelosarcoma, lymphosarcoma or reticulum-cell sarcoma) with primitive cells in the blood smear corresponding to the type of tumor This occurs not infrequently in multiple myeloma, which in reality is a tumor of plasma cells Plasma-cell leukemia is occasionally described, as in recent reports by Patek and Castle (*Am J M Sc* 191 788, 1936), Jores and Bruns (*Folia haemat* 55 277, 1936) and Fleischacker and Klima (*Folia haemat* 56 5, 1936) The difference from the pathologist's standpoint between a local tumor composed of blood cells and the diffuse process called leukemia is often indistinguishable The diagnosis of leukemia is thus in reality a clinical one which may indicate a local tumor with metastasizing cells in the blood or a generalized disease without local tumors

Instead of the paradoxical term aleukemic leukemia, Weil, Isch-Wall and Perlès (*Presse Med* 44 41, 1936) suggest the term "cryptoleukemia," which they feel can often be diagnosed by splenic puncture Although this is doubtless quite a simple procedure, the reviewer has hesitated to adopt this test and has instead carried out sternal bone-marrow biopsy In various disorders in which the spleen is involved, much can be learned from study of the marrow

Many case reports of monocytic leukemia continue to be published One of the best of these, with careful descriptions of the postmortem findings and blood picture, is that of Kato (*J Pediat*

8 679, 1936) Kracke and Garver (*Am J M Technol* 2 81, 1936) make some important observations on the diagnosis of leukemia in which the recommendation is made that the physician and not the technician be responsible for the diagnosis The reviewer can confirm Kracke's experience that the primitive cells—histiocytes, myeloblasts, lymphoblasts—of acute leukemia are more often than not called "large mononuclears" or "large lymphocytes," and thus their diagnostic significance is not realized This happens more often with slide smears, which are frequently too thick for the careful study of individual cells, than with smears made with cover slips In cases of leukemia with normal or low leukocyte counts, study of the "buffy coat" of the blood after it has been centrifuged may reveal many primitive cells, difficult to find otherwise

Keilhack (*Folia haemat* 55 406, 1936) reports an interesting case of chronic aleukemic myelosis with hyperproteinemia High blood proteins have heretofore been reported, aside from kala-azar, only in association with plasma-cell tumors (multiple myeloma) Keilhack's report, in which the total protein was 7.43, albumin 1.80 and globulin 5.16 per cent, is the first showing increased globulins in myeloid leukemia There is a possibility, however, that the diagnosis was not correct since the lymph nodes were greatly enlarged, a very unusual finding in this disease Goldhamer and Barney (*J A M A* 107 1041, 1936) report a case of myelogenous leukemia with cutaneous involvement, which is rare in this disease, although much commoner in the chronic lymphoid type (A generalized macular, infiltrative eruption is commonly seen in acute monocytic leukemia)

The treatment of leukemia remains as discouraging as ever The acute types are better given large doses of sedatives and thus made relatively comfortable Transfusions, x-ray therapy and liver extract often distress the patient without modifying the disease in the slightest X-ray treatment in the chronic cases should be given only when it seems essential for the relief of symptoms I have often seen a relatively healthy patient become bedridden because of too meddlesome therapeutics in this direction Too often the blood count and not the patient is treated X-ray therapy, judiciously handled by the radiologist in close collaboration with the internist, is often of great value Spray treatment or total roentgen therapy seems to be the present method of choice with many radiologists It is useful, as Belot (*Strahlentherapie* 56 560, 1936) points out, in disorders which involve the entire organism, and therefore in leukemia In the reviewer's experience, spray treatment has been disappointing H F Friedman (personal communication) states that he has obtained better results

with the use of intensive local dosage given in turn to various areas of the body until the whole body has been covered. Stephens and Lawrence (*Ann Int Med* 9 1488, 1936) report on their experience with Fowler's solution in the treatment of chronic myeloid leukemia. They recommend it as an effective palliative agent comparing favorably with x-ray therapy. It can perhaps be used most advantageously in conjunction with or alternating with irradiation. Where x-ray therapy is not readily available, the drug may well be used, although its effects on the platelets are often disastrous. The reviewer has discarded its use because of the frequency of toxic effects. Middleton, Meyer and Pohle (*Radiology* 26 586, 1936) give their experience with radiotherapy in leukemia, with particular reference to the effect on the basal metabolic rate. The metabolism, which is commonly elevated in chronic lymphoid leukemia, may act as one of the guides in further therapy. The authors stress the necessity for individualization of therapy.

TUMORS OF THE WHITE CELLS

Krumbhaar (*J A M A* 106 286, 1936), for want of a better term,* proposes that a host of conditions, widely dissimilar in morphology and etiology and in many other ways, be called "lymphomatoid diseases" the various leukemias, the various sarcomas, mycosis fungoides, Hodgkin's disease, agranulocytosis, Cooley's anemia, infectious hemolytic anemia, hepatic thrombosis and von Jaksch's disease. Although this conception may rightly be criticized, the article deserves careful reading, because many apparently unrelated conditions are brought together and discussed in a manner both philosophic and profitable. His classification of "primary myelogenous, lymphocytic and reticular disorders" is quite in keeping with the classifications which have been offered in these reviews in the past two years. Thus there are three blood-forming tissues: bone marrow, lymphoid tissue, and reticuloendothelium. All may be subject to generalized (leukemic) or localized (sarcomatous), leukemic or aleukemic, processes, or to combinations of these. This sort of classification is more in line with the statement which Krumbhaar quotes James Ewing as making in 1927: "Although we may not be able to find clear differences in all cases, how are we going to make progress by throwing them all into one category? I should rather see the most minute differences emphasized and a classification based upon these, until the time when the etiologic factors unify or subdivide the entire group." For

the tumors of the blood cells, as simple a classification as any is that given in last year's review. This may be repeated here:

TISSUE	HIGHLY MALIGNANT	LESS MALIGNANT
Bone marrow	Myelosarcoma (chloroma)	Myeloma (not multiple myeloma)
Lymphoid tissue	Lymphosarcoma	Lymphoma Plasmacytoma (multiple myeloma)
Reticulo-endothelium	Reticulum-cell sarcoma Hodgkin's disease.	Reticulo-endothelioma

Jackson, Parker and Brues (*Am J M Sc* 191 1, 1936) describe under the Boston term of "malignant lymphoma" of the tonsil 37 cases, including reticulum-cell sarcoma, lymphocytoma, Hodgkin's disease, lymphosarcoma, giant-follicle lymphoma and plasmacytoma. The progress of these cases is extremely variable and unpredictable, although it is practically always downhill to death. The number of mitoses per oil-immersion field gave some general indication of the progress. Thus, the patients with ten mitoses per oil-immersion field died in less than six months, those with an average of one or less died in three years or over. The authors warn against the deceptive character of the initial radiosensitivity to x-ray therapy.

Hodgkin's Disease The tendency is more and more to group this disease among the proliferative lesions of the reticuloendothelial system. Although the disease usually originates in the lymph nodes, it is not necessarily a disorder of lymphoid tissue per se, since the lymph nodes contain two widely different types of cells: lymphocytes and reticulum cells. The latter cells differ histologically and functionally from the lymphocytes, and make up, together with similar cells in the bone marrow, the liver and the spleen, the reticuloendothelial system. The reticulum production in Hodgkin's disease and the formation of giant cells are quite characteristic of reticulum-cell rather than lymphocytic proliferation.

Rosenberg and Bloch (*J A M A* 106 1156, 1936) and Goldstein (*Am J M Sc* 191 775, 1936) report their results with the Gordon test in Hodgkin's disease. The test consists briefly in the injection of an emulsion of the suspected lymph node into the brains of rabbits. In a positive reaction the rabbit develops various types of cerebral reactions such as ataxia, spasticity and convulsions. Friedmann in 1934 reported that this test could be obtained with normal bone marrow. Until very recently, the pathogenesis of the test had been unknown. However, in May, 1937, Turner and Jackson (*J Clin Investigation* 16 657, 1937)

*He does not like the terms commonly used in Boston: lymphoblastoma and malignant lymphoma.

showed quite conclusively that the reaction is specific only insofar as the eosinophil is concerned, and will be positive only when eosinophilia is present. Eosinophilia from a variety of conditions will produce the same kind of paralytic action in rabbits. This explains why normal bone marrow with its content of eosinophils gives a positive test and why the fibrotic lymph node of Hodgkin's disease, without eosinophils, gives a negative reaction. Weil, Isch-Wall and Perlès (*Bull et mém Soc med d hop de Paris* 52 1006, 1936) recommend the technic of lymph-node puncture which they have used with excellent diagnostic results in 20 cases. In each instance they controlled their observations with actual biopsy. The principal diagnostic criteria in the puncture material were endothelial elements and authentic giant cells of Sternberg. The reviewer can confirm the simplicity and accuracy of this simple procedure, which might well be generally adopted although for the first year or so it should always be checked with the actual biopsy of a node. The method consists in puncturing an accessible lymph node with an 18 to 20 gauge needle and drawing up a very small amount of material into the needle by the use of suction from a 20-cc syringe. The resultant bits of material are smeared on glass slides which are stained with Wright's or Giemsa stain. Our attention was first drawn to this method by Alfredo Pavlovsky, of Buenos Aires, who has written a monograph on the subject (*Ann d Inst Mun de Rad y Fis Terap* 1 71, 1934). For simple bedside differential diagnosis of lymphosarcoma, Hodgkin's disease, tuberculous adenitis and infectious adenitis the method may be invaluable.

Roth and Watkins (*Ann Int Med* 9 1365, 1936) point out from a study of 40 cases that there is no specific morphologic blood picture diagnostic of Hodgkin's disease. This is quite true. Typical blood pictures are seen only when one knows the diagnosis in advance.

Very little that is new regarding either the diagnosis, pathology or treatment of the disease has been written. An interesting paper is contributed by Ebbehj (*Hospitaltid* 79 253, 1936), who describes minutely the findings in 44 verified cases. In the lungs the disorder may be confused with tuberculosis. The bony system may be involved, generally in the second year of the disease, bony defects are generally the rule, although osteoblastic and sclerosing forms are found. Jacoby, Peirce and Hildreth (*Am J Roentgenol* 36 165, 1936) report on the x-ray treatment of 161 cases within the past decade. Definite

extension of life was induced, as compared with untreated patients, systemic (spray) irradiation was of no greater effect than repeated local treatment, future figures may be better because of improved and more intensive methods of therapy.

HEMORRHAGIC DISEASES (HEMORRHAGIC DIATHESIS)

It is customary to group under the designation of hemorrhagic diathesis a number of disorders in which the only common factor is the tendency to abnormal bleeding. The following classification is offered since it has proved useful in teaching and in the clinic.

- 1 Disturbances of the clotting mechanism
Hemophilia, pseudo-hemophilia, increased coagulation time of jaundice.
- 2 Purpura.
 - a. With deficiency in blood platelets (thrombocytopenic form)
 - (1) Primary, idiopathic or essential
 - (2) Secondary to involvement of bone marrow by a destructive process
Chemical—benzol, arsenic, x-ray, radium, and so forth
Carcinoma and sarcoma
Leukemia.
Gaucher's disease.
 - b. Without deficiency in blood platelets (vascular form)
Anaphylactoid, senile, toxic, nutritional, scorbutic, and so forth.
- 3 Well substantiated vascular defects
Hereditary hemorrhagic telangiectasis, other forms of telangiectasia

Disturbances of the Clotting Mechanism Despite an enormous amount of investigation, little success has been attained in the elucidation of the defective clotting mechanism in hemophilia. Patek and Stetson (*J Clin Investigation* 15 531, 1936) seem, however, to be making progress in this difficult field. These authors state that "the one abnormality constantly found in hemophilia is an inability of the blood to coagulate in a normal manner," a defect demonstrable in the prolonged clotting time. They therefore set out to find what it was that caused this prolongation. It was assumed further that normal blood contains a substance which either supplies a clotting factor lacking from hemophilic blood or which counteracts a mechanism inhibiting coagulation of the blood in hemophilia. The problem was to find this substance, and to do this necessitated the abandonment of many of the previous theoretical concepts regarding the mechanisms of coagulation. The coagulation time as determined by a standard technic was tested in normal and hemophilic blood before and after the use of various test substances. From these tests

these writers conclude that "there is a substance in normal blood which in small quantity effectively reduced the clotting time of hemophilic blood, both in vitro and in vivo, this substance is present in platelet-free plasma and in the plasma of thrombopenic purpura" Further experiments demonstrated that the platelets of hemophilia were normal and that the clotting factor of normal plasma had nothing whatever to do with the platelets or their degradation products Further work along these lines is being carried out The defective substance in the serum is apparently linked up with "prothrombin" and is present in the globulin portion of the blood Patek and Taylor (*Science* 84 271, 1936) continue their investigations in this very important problem

Gray and Ivy (*Am J Digest Dis & Nutrition* 2 368, 1935) studied the serum calcium in cases of jaundice, and found that there was no change in either the diffusible or nondiffusible forms From this they inferred that the calcium metabolism was not responsible for the increased bleeding in jaundice, but that it was probably related directly to the degree of liver damage (This might link up with a fibrinogen defect as postulated by Patek and Stetson, which has been known to be present in severe liver damage) As stated in last year's review, Quick, Brown and Bancroft (*Am J M Sc* 190 501, 1935) set out to find the coagulation defect in cases of jaundice which they thought resided in an alteration in the prothrombin content of the blood Unfortunately they came to no definite conclusion on this point, although their results were suggestive

Transfusion of whole blood or of normal blood plasma is at present the best therapeutic measure we have for hemophilia Patek and Stetson have already demonstrated that relatively small amounts of blood plasma kept at icebox temperature are effective in rapidly shortening the clotting time in cases of hemophilia To forestall bleeding in cases of severe jaundice which necessitate operation, Judd, Snell and Hoerner (*J A M A* 105 1653, 1935) recommend the use of repeated transfusions, preferably before operation Other methods for shortening the clotting time are still being tried Eley, Green and McKhann (*J Pediat* 8 135, 1936) gave an extract of human placenta to 15 children with hemophilia, either orally or by the intramuscular route, 11 cases showed a satisfactory response, with reduction of the clotting time to normal limits Macfarlane (*St Barth Hosp Rep* 68 229, 1935) recommends the use of Russell-viper venom for application locally to stop bleeding in cases of hemophilia This venom was obtained from vipers in the collection of the Zoological Society of London and was effective in clotting

hemophilic blood in a concentration of 1 1,000,000 within six minutes It was used locally on external wounds, or wounds of the gums after dental extractions, with success in 5 of 7 cases Barnett (*Proc Roy Soc Med* 28 1469, 1935) reported similar results with the same venom applied locally in 6 cases of hemophilia These results are similar to those obtained by Rosenfeld and Lenke (*Am J M Sc* 190 779, 1935), who used the venom of the Australian tiger snake, which readily clots 12,800,000 times its weight of heavily citrated or oxalated blood These authors find that tiger-snake venom is superior to Russell-viper venom in many important respects Timperley, Naish and Clark (*Lancet* 2 1142, 1936) report the discovery of a nonprotein substance derived from egg white which when given intravenously to cases of hemophilia shortened the clotting time and stopped further progress of symptoms

Purpura It is possible that bleeding does not occur under the skin in the form of petechiae or ecchymoses unless there is an associated (hypothetical) vascular defect It is also possible that these hypothetical vascular defects may be initiated by the same stimuli which produce the reduction in blood platelets Speculation aside, however, it is usually possible to divide purpura into two main types with and without platelet deficiency

The more one studies *thrombocytopenic purpura* of various types, the more one is disinclined to call anything essential or primary or idiopathic. Causes are rapidly being discovered for the primary anemias of another decade, and the same sort of evolutionary change seems to be developing with thrombocytopenic purpura Thus, in recent years the sedative, Sedormid, has been implicated in an increasing number of cases (Boas and Erf, *New York State J Med* 36 491, 1936, Peck, Rosenthal and Erf, *J A M A* 106 1783, 1936) Neoarsphenamine has again been implicated (Falconer, Epstein and Wever, *Arch Int Med* 58 495, 1936) in 3 cases which developed severe toxic constitutional reactions accompanied by purpura hemorrhagica These authors felt that there was a distinct relation between the nitritoid crises of the arsphenamines and the development of thrombocytopenic purpura hemorrhagica Other drugs which have been incriminated as the probable causes of certain cases of purpura are quinine, chrysarobin, Nirvanol, gold salts and benzene (Cf Patek *Am J M Sc* 191 723, 1936) It is likely that the development of purpura in these cases is in the nature of an allergic reaction, the marrow becoming involved by the "toxic" factor in much the same way as the leukocytes

are involved in agranulocytosis, as previously noted. The observation by the reviewer of a series of 4 cases of thrombocytopenic purpura following major operative procedures leads to speculation concerning the possible role of the barbiturate preparations that are so widely used for preoperative medication.

Despite observation of cases in which an etiologic factor was present, it is conceded that the majority of the cases present no discernible causative mechanism. In those cases occurring usually in girls and developing at about the time of onset of the menstrual cycle, a possible endocrine factor may be postulated. This is strengthened by the fact that in certain cases the platelet count becomes greatly diminished with the menstrual periods. Minot (*Am J M Sc* 192 445, 1936) reports a group of 3 cases occurring periodically with menstruation, and discusses the possibility of an altered endocrine function.

In the idiopathic cases there is a great deal of speculation regarding the mechanisms involved. In common with many authors, Doan, Curtis and Wiseman (*J A M A* 105 1567, 1935) put the significant question "Does the spleen inhibit the formation of platelets in the bone marrow or does it destroy them overly fast?" They do not attempt to answer the question completely, but suggest that the spleen may hold the key position in the so-called hemolytotoeic equilibrium (a term first used by Krumbhaar in 1923). Several investigators have attempted to reproduce the disease experimentally in animals by the use of antiplatelet extracts. Thus, Tocantins (*Arch Path* 21 69, 1936, and *Ann Int Med* 9 838, 1936) induced thrombopenic purpura in dogs by the use of an antiplatelet serum. With the production of a very low platelet count, several tests were performed: bleeding time, clot retraction, tourniquet test, and so forth. The correlation of the level of the platelet count with the bleeding time was not so great as that with the degree of clot retraction*. Filo (*Sang* 10 74, 1936) produced thrombocytopenia in rabbits by the use of a guinea-pig antiplatelet serum. He then studied the bone marrow and found that the megakaryocytes were still present in normal numbers along with various types of nuclear changes. The bleeding time in all the experiments was found to be prolonged. Removing the spleen had no effect on this type of purpura. Kryukof (*Sang* 9 363, 1935) reports a case of thrombocytopenic purpura with bone-marrow biopsy, although there were no platelets

in the peripheral blood, the marrow showed many megakaryocytes.

Although their article is not strictly concerned with purpura but with a careful study of latent and outspoken scurvy, Wright and Lilienfeld (*Arch Int Med* 57 241, 1936) make an important contribution relative to the diagnosis and study of these cases in the form of a standardized tourniquet test (see under "Methods").

With reference to therapy, splenectomy continues to hold its place as a reliable, although radical, form of treatment. Doan, Curtis and Wiseman advance a great deal of clinical data to show the value of this procedure. In a very careful follow-up of 21 cases, 10 splenectomized and 11 treated conservatively by various medical measures, Brown and Elliott (*J A M A* 107 1781, 1936) make the following summary:

In the splenectomized group 80 per cent of the cases were vastly improved or arrested, while the same can be said of only 27 per cent of the control series. It will be seen further that under improved but by no means arrested we find 10 per cent of the operative and 18 per cent of the controls, and that under unimproved or died we find 10 per cent of the splenectomized and 54 per cent of the non splenectomized. In short, we have found three times as many excellent results among the operative group as among the controls, and five times as many poor results among the controls as among the operative group.

Except in the fulminating case requiring emergency splenectomy, it is probably advisable to try the various available medical procedures first. Mettier, Stone and Purviance (*Am J M Sc* 191 794, 1936) treated 7 patients by x-ray therapy over the spleen. In 6 cases the platelet count rose to high limits within twenty-four to forty-eight hours after beginning treatment. The authors cannot explain the mechanism of the reaction, which is usually a transitory and not a curative phenomenon. Moccasin-snake venom is, according to Peck and Rosenthal (*J A M A* 104 1066, 1935), effective in some cases and ineffective in others. Lowenburg and Ginsburg (*J A M A* 106 1779, 1936) produced hypercalcemia in 2 patients (children) by the use of parathyroid extract in dosage of 3 cc (60 units) given daily subcutaneously. Calcium gluconate, 10 cc, was given intramuscularly at the same time. In both cases, the patients developed severe symptoms of hypercalcemia: apathy, lethargy and persistent vomiting associated with a marked increase in the serum calcium. Simultaneously with the development of these symptoms there was a striking diminution in bleeding time, an improved clot retraction and a rise in platelet count. This method deserves further trial. Many writers refer to the use of ascorbic acid (vitamin C). Thus Dreyfus (*Presse med* 44 589, 1936) reports 2 cases in child-

*The bleed n. time is obtained by puncturing the ear with a large bore needle and measuring the time for bleeding to stop. The normal time is one to three minutes; the period increases with diminution in platelets. Retraction of the clot normally occurs in a test tube when blood is allowed to coagulate. With deficiency in platelets the clot retracts very slightly if at all in twenty-four hours.

hood responding to intravenous vitamin C. Many of these reports are uncontrolled and not convincing. In the careful observations of Wright and Lilienfeld there was no improvement in thrombocytopenic purpura following this method of therapy.

Non-thrombocytopenic vascular purpura is apparently caused by a defect of the capillary wall, since the platelets, bleeding time, and clot retraction are all normal. The abnormality of the vessel wall may be due to some well-defined cause such as deficiency in vitamin C or a severe allergic reaction (uremia), or may be completely idiopathic.

The reviewer has seen many women with ecchymotic spots, which usually appear about the time of the menstrual period and which are of no significance. Calcium salts may be of some value in these cases. At times one is faced with the problem of severe postoperative bleeding in a patient whose tests (bleeding time, clotting time, platelet count, and so forth) are all negative but whose tourniquet test may be positive. In these cases it is the reviewer's impression that antivenin (Mulford), given in one dose of 10 cc intramuscularly, followed by moccasin-snake venom in rapidly increasing doses, is of distinct benefit.

TRACY B. MALLORY, M.D., *Editor*

CASE 24011

PRESENTATION OF CASE

First Admission A sixty-two-year-old, white, native-born watchmaker entered the hospital with a complaint of weakness.

Two months before entry he began to feel weak and tired and became slightly dyspneic. He also noticed increasing constipation with change in the character of his stools. About that time he had a single episode of dizziness and almost fainted on two occasions. He took a cathartic and passed a large amount of clotted blood by rectum. Following this he felt quite tired, his dyspnea increased and he had a temperature of 101°F. However, the stools became normal and remained so until the time of entry. Four days after the acute episode he consulted his physician, who told him that his stool gave a 3+ guaiac test and that the red cell count of his blood was 2,500,000. He was sent to a hospital, given a transfusion, and put on a milk and cream diet. X-ray studies at that time were said to show a tumor lying between the bladder and the rectum. He was given a course of x-ray treatment over a six-week period and was told that the tumor was getting progressively smaller. For the two weeks prior to entry to this hospital he had no symptoms except fatigue and dyspnea on exertion. During his illness he had lost 10 lb in weight.

The past history and family history were essentially negative.

Physical examination revealed an emaciated elderly man in no acute discomfort, with dry, lemon-tinted skin. The heart and lungs were negative. The blood pressure was 120 systolic, 80 diastolic. There were bilateral indirect inguinal hernias and undescended testes. The testes could be palpated just external to the inguinal rings. The right testis was slightly tender. On rectal examination the right lobe of the prostate was found to be moderately enlarged, smooth and non-tender. Both lobes were definitely firmer than normal. High on the anterior aspect of the rectal wall there was a hard, irregular, fixed, pelvic mass, measuring about 6 to 8 cm in diameter, which did not descend on "bearing down," as in defecation. No mucosal involvement could be made out, but the examining finger could palpate only the inferior surface of the mass.

The temperature was 98.6°F., the pulse 60. The respirations were 20.

The urine examination was negative. The blood showed a red cell count of 4,360,000 with 75 per cent hemoglobin. The white cell count was 8100, 61 per cent polymorphonuclears. Two guaiac tests on the stools were negative. A blood Hinton test was negative. The blood sugar was 110 mg per cent, and the nonprotein nitrogen 28 mg per cent.

A gastrointestinal x-ray series revealed thickening of the gastric mucosa with elongation of the pyloric valve, but no areas of active ulceration or other lesions could be demonstrated. A barium enema and chest plate were negative.

He was discharged unimproved on the fourth day.

Second Admission (two and a half months later) During the interval he was essentially well, except for a sensation of a mass in his pelvis which he felt in the region of the rectum on sitting down. He had no tarry or bloody stools or change in his bowel habits, and he gained 6 lb in weight.

Physical examination was essentially the same as before, except that the mass felt by rectal examination seemed to be larger. Its growth had been downward into the rectovesical pouch, so that its inferior margin reached the upper border of the prostate. The rectal mucosa overlying it felt edematous but not ulcerated.

The temperature was 99°F., the pulse 65. The respirations were 20.

The urine examination was negative. The blood showed a red cell count of 4,190,000, 75 per cent hemoglobin. The white cell count was 10,900, 82 per cent polymorphonuclears.

On the second day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. RICHARD H. SWEET This case is one of a sixty-two-year-old man with a relatively short duration of symptoms—two months—starting with a feeling of being weak and tired and then developing slight dyspnea. He noticed increasing constipation and a change in the character of the stools. About that time he had a sudden episode of dizziness and almost fainted on two occasions.

This is a most interesting history. He must certainly have had a massive hemorrhage to account for this episode of dizziness and the passing of clots and the fact that the doctor found the red count so low that it was necessary to transfuse. I think that we also have some evidence of previous hemorrhage, possibly chronic blood loss, from the fact that he was becoming tired and developing dysp-

nea, although it may have been secondary in some other way to the lesion which he developed. From the story we should expect to find that he had a lesion in the stomach or high in the intestinal tract, but the x-ray located it between the bladder and the rectum.

Another interesting feature about this story is the result of the x-ray treatment. A treatment directed over the pelvis produced marked regression in the size of the tumor in a short space of time. There are very few malignant tumors which will do that. The only one I know of is lymphoblastoma. Perhaps Dr Hampton will help on that later. Lymphoma will respond rapidly to x-ray, but how to connect this pelvic mass with his gastrointestinal hemorrhage is the problem.

On physical examination here in the hospital we find that he had lemon-tinted skin, suggesting anemia or possibly malignant disease. I think we can attach no particular significance to the enlarged right lobe of the prostate. It may have been due to benign hypertrophy. There is no note of a proctoscopic examination, which might have helped us in that an ulceration might have been seen.

DR TRACY B MALLORY: Proctoscopy was attempted, but it did not help because the instrument was blocked by the edge of the tumor and the observer was unable to see the mucosa overlying the mass. The rectum below the point of obstruction was normal.

DR SWEET: With this pelvic mass it is curious that the barium enema was negative, and if we are going to assume that he had a gastric lesion and a pelvic mass we ought to find something by x-ray in the stomach. If he had a carcinoma of the stomach and a secondary pelvic tumor,— a gravitating one, if you wish to call it that,— from cancer, the tumor in the stomach ought to be obvious.

X-RAY INTERPRETATION

DR AUBREY O HAMPTON: When were the x-ray treatments given?

DR MALLORY: Before he came in.

DR HAMPTON: I cannot find the mass in this film though there is something wrong with the rectum. It is a small displaced rectum. It is as small as the sigmoid, with no ampulla, and in the upper end where a loop of sigmoid crosses it there seems to be a defect. But on this film, which I assume to be a local view of that area, I do not see any defect. The wall of the rectum looks flat and rather rigid. I have a feeling that this is a defect, but it is not very plain. I could only guess that he might have an intrinsic lesion of his rectum. This other lesion in the duodenum or pyloric valve looks like an ulcer of the base of the duodenum at the distal margin of the valve. It

does not appear to be active. The pyloric valve is long and thread-like and the duodenum shows an irregularity across the base. There is a little projection in the base of the cap that interests me. I think probably you can say that he had a duodenal peptic ulcer which has healed.

DR SWEET: What portion of the duodenum would you say it was in?

DR HAMPTON: I should say in the first portion of the duodenum, near the valve, although I am not too sure.

DIFFERENTIAL DIAGNOSIS (CONTINUED)

DR SWEET: Dr Hampton has helped us considerably because I have a feeling now that the pelvic mass and the gastric lesion are not connected. When I read the history I thought that I should try to make some connection between these two lesions. We can assume that he had a scarred duodenum from an old healed ulcer. I think we can very readily assume that the pelvic mass is not associated with it.

Whether the massive hemorrhage was from high in the gastrointestinal tract or from the colon is not quite so easy to decide, because it seems from the history to have been old blood. It may very well have been blood which accumulated in the colon from an ulceration in the colon itself and then passed when he took the cathartic. I presume, though, if it were old blood, it should have been from higher in the intestinal tract. Unless this ulcer of the duodenum was on the posterior wall it is unlikely that it was the source of a massive hemorrhage. I do not recall ever having seen duodenal ulcers that were not posterior cause a hemorrhage severe enough to make a man faint and lose that much blood. If he had an ulcer we can be sure it was healed and not an active posterior-wall ulcer.

I think we must assume that he had a massive hemorrhage from the mass which was found in the pelvis. This mass was felt by rectum, but they did not see a lesion. That is not surprising because it is quite possible to have a mass in the sigmoid which cannot be seen or only the lower edge of which can be seen. The rectal mucosa seemed to be normal. It is possible to feel and with a proctoscope to see a bulging caused by a mass in another portion of bowel, in other words, from the rectosigmoid one can often feel or indirectly see a mass in a loop which lies against the portion which you are examining. At any rate, this mass was next to the rectum and probably involved the rectosigmoid or sigmoid, and I should say that it was probably the source of the hemorrhage. In my experience, carcinoma of the colon is not very apt to act this way. Massive hemorrhages into

the rectum or colon from a carcinoma are very unusual. They are unusual in the stomach, although this summer I had a patient with massive gastric hemorrhage who had carcinoma. The tumor of the gastrointestinal tract that is most apt to cause hemorrhage of this sort is lymphoblastoma. So, having had the assurance of the x-ray report, I think we can conclude that the lesion for which they operated was a lesion in the pelvis which probably involved the colon. Whether it started there or not, I am not certain, but I will guess that it was a tumor of the lymphoma series.

DR WILLIAM B BREED: Why do you rule out so quickly the duodenum as a source of the hemorrhage? He might have bled two months previously and the lesion healed by this time.

DR SWEET: I thought of that when I read the note about his coming in relatively soon. It was a matter of several weeks.

DR BREED: It was two months.

DR SWEET: I assumed that the duodenum would not look so scarred and contracted if the ulcer were associated with hemorrhage, moreover I am not sure where the ulcer is. I do not feel very enthusiastic about making a diagnosis of massive hemorrhage from duodenal ulcer unless it is on the posterior wall.

CLINICAL DISCUSSION

DR HORACE K. SOWLES: What is the chance of tumor of one of the undescended testicles?

DR MALLORY: They were undescended but were felt and seemed to be normal.

DR WYMAN RICHARDSON: I am not sure that the idea of carcinoma of the stomach with metastases to the pelvis is not worth thinking of a little more.

DR SWEET: I thought of that first, but cast it out.

A PHYSICIAN: Does anyone know how much treatment he had by x-ray?

DR MALLORY: No. Moreover, we have only the statement that he had been told that the mass decreased in size, we have no objective proof.

DR REGINALD H SMITHWICK: This was a very puzzling case to me. I was rather inclined to explain the hemorrhage on the basis of the lesion in the duodenum because the pelvic mass definitely seemed to be extrinsic so far as the rectum itself was concerned. It lay in the pelvis just above the prostate and felt very much as do the retroperitoneal gravitating masses that Dr Sweet mentioned. The persistently negative guaiacs in the stools and our inability to demonstrate ulceration by proctoscope, although examination was unsatisfactory, made me feel that he probably had a lymphoma of some sort which did not necessarily

extend through the wall of the rectum. On exploration we found a mass the size of one's fist lying in the bottom of the pelvis and completely filling it. It was very firmly fixed. The rectosigmoid was densely adherent to it, and one loop of small intestine was knuckled down into it. It seemed at first inoperable. A biopsy was taken and Dr Castleman reported a malignant but slowly growing tumor, definitely not lymphoma. For that reason it seemed worthwhile to try to take it out. All the pelvic peritoneum was removed, together with the mass, separating both ureters from it over a distance of 10 cm on each side. The tumor was adherent to the prostate and bladder, and was separated from them. His rectosigmoid was quite adherent to the mass, chiefly in the mesenteric portion, however, so that one leaf of the mesentery could be removed without destroying the blood supply to the large intestine. It was finally obvious that the growth arose in the loop of small intestine which knuckled into the tumor. This was resected and on opening the specimen, a 2 cm ulcer was found in the wall of the intestine, opening into a cavity about the size of one's thumb which projected into the center of the tumor. On further inspection that loop of small intestine was found to be about in the middle of the intestinal tract. He had no metastases, and a very cursory exploration of the stomach and duodenum failed to reveal evidence of any lesion.

PREOPERATIVE DIAGNOSIS

Retroperitoneal lymphoma

DR SWEET'S DIAGNOSIS

Lymphoma involving the rectum

ANATOMIC DIAGNOSIS

Neurogenic fibrosarcoma of the ileum

PATHOLOGICAL DISCUSSION

DR MALLORY: The tumor we received was a roughly spherical one, fairly completely surrounding a loop of the ileum. As Dr Smithwick told you, it had a deep crater-like cavity in the center. On microscopic examination it was a spindle-cell sarcoma growing at a moderate rate of speed. There were some mitotic figures, and occasional though not very many mononuclear cells. I should say it was of neural origin. Grossly it closely resembled the leiomyomas or leiomyosarcomas that we see in the stomach where deep shaggy craters develop in the center of the tumor. The prognosis in this case is somewhat difficult to make, but I think it is perfectly possible that he may have been cured.

DR HAMPTON: I remember this case now. A

six hour examination was done. The bowel was examined and nothing was found. Furthermore, he was treated with 3000 r, which is about twice as much as you would ordinarily give to lymphoma, so that the tumor responded to quite heavy radiation rather than to a lymphoma dose.

CASE 24012

PRESENTATION OF CASE

A fifty-eight-year-old American housewife was admitted complaining of increasing generalized edema of two years' duration.

Fifteen years before entry she noticed dyspnea on exertion and began using two pillows at night. About twelve years before entry an oculist examined her and advised her to see a physician, who told her that she had "pus in her kidneys." He treated her with "nephritis" tablets and put her on a diet consisting of beef, lettuce and hot water, which she followed for eight months. She improved somewhat under this regime and for the next seven years was quite well except for weakness. About five years before entry she began to notice urinary frequency and nocturia which persisted without dysuria or hematuria. About that time she had an attack of terrific precordial pain which radiated to the back, left shoulder and left arm and was accompanied by a feeling of choking, palpitation and irregular beating of the heart. The attack was relieved by complete rest, nitroglycerin and morphine. In the succeeding five years she had five similar attacks, none of which were related to exertion or any other circumstance. Four years before entry she suddenly developed paralysis of the entire right side of her body with dysphagia and dysarthria. The condition cleared up completely in the course of a few months. She was told at that time that she had a blood pressure of 260. In the next two years her dyspnea and weakness gradually increased until she was unable to do all her housework. Two years before entry she first noticed swelling of her ankles. This edema gradually spread up her body, and even her face became puffy, although no edema of the eyelids was noticed. Ten months before entry she had become so dyspneic that she was no longer able to lie flat in bed, and for the five months before entry she had to sleep in an armchair. The legs became immense because of edema and she gained 50 lb in weight in spite of treatment with two tablets of digitalis daily, frequent injections of salyrgan and a very much restricted fluid intake. Shortly before entry the skin of her legs cracked and began oozing fluid. She had recently noticed some blurring of vision.

She had no hemoptysis, headache, nosebleeds or

other significant symptoms except as noted above. Since childhood she had had mild asthmatic attacks, chiefly in the summer, which had largely disappeared about ten years before entry. About that time she had an attack of pain, swelling and tenderness of both knee joints, which was treated with braces, bandages and special shoes and cleared up after two months. Eight years before entry she developed pain and tenderness in the left flank associated with a tender, palpable mass which was demonstrated by x-ray. A laparotomy was done at an outside hospital and she was told that a large displaced liver had been pushed back into normal position.

The family history was essentially negative except for one stillbirth. She had three normal children.

Physical examination revealed a huge woman sitting upright in bed, breathing somewhat rapidly but not showing cyanosis. There was very marked edema of the feet, legs, abdominal wall and sacral region, slight edema of the hands, but no edema of the face. On both tibiae there were red, non-indurated, excoriated areas oozing clear fluid. The fundi showed very marked tortuosity and narrowing of the arteries with arteriovenous nicking and many exudative areas. There was no papilledema or fresh hemorrhages. The veins of the neck and chest wall were slightly dilated. The pulse was very irregular, and the blood pressure was 158 systolic, 110 diastolic. The heart was enlarged both to the right and left, the sounds were of good quality, and a soft systolic murmur could be heard over the pulmonic area. The lungs had many crackling rales at the left base and a few at the right base. There was very marked ascites, and the liver edge was slightly tender and palpable two fingerbreadths below the costal margin.

The temperature was 98°F, the pulse 84. The respirations were 28.

The urine had a specific gravity of 1.030, and contained a large trace of albumin, with 5 to 10 red blood cells and 20 to 30 white cells per high-power field and granular casts. The blood showed a red cell count of 4,490,000, 75 per cent hemoglobin. The white cell count was 10,850, 73 per cent polymorphonuclears. The stool gave a 2+guaiac test. A blood Hinton test was negative. The nonprotein nitrogen of the blood serum was 34 mg, the protein 4.8 gm., and the cholesterol 175 mg per cent. The Takata-Ara test was negative. The van den Bergh was normal, indirect. An electrocardiogram showed auricular fibrillation, diphasic T₁ and T₂, upright T₃ and T₄, and moderate left-axis deviation.

An x-ray of the chest showed diffuse prominence of the blood vessels throughout the lung

with diminished radiance at both bases but no appreciable amount of pleural fluid. The heart was grossly enlarged, chiefly across the base, and the aorta showed calcification.

She was fully digitalized and given four injections of salyrgan at two-day intervals. This caused a good diuresis, and after a week in the hospital most of the ascites had disappeared. Southey tubes were put in her legs on the eighth day. On the tenth day she died quietly in her sleep.

DIFFERENTIAL DIAGNOSIS

DR R. EARLE GLENDY. In considering this case it is evident from the history that some cardiovascular disease had been present for about fifteen years and had progressed insidiously for most of that time until her death. Dyspnea on effort and orthopnea were first noted fifteen years before her admission to the hospital, no doubt indicating impairment of her myocardial reserve. Subsequently, at the age of forty-six, an examination of her eyes revealed what we may presume to be vascular changes in the fundi, for she was placed on a "nephritic" regime. The improvement that followed was probably due to dietary restriction. There is no record of her blood pressure when first seen by a physician, but in light of subsequent events it is probably safe to surmise that it was high and had been for some time.

For five years preceding her death she had urinary frequency and nocturia. This would indicate that her urine was increased in amount and probably of low specific gravity—altogether typical of the form of nephritis in which cardiovascular disturbances are interwoven with renal changes and which might be more properly called a cardiovascular-renal disturbance. In such cases hypertension is almost invariably present, this further suggests an elevation of the blood pressure of some standing.

Among other things, she had six attacks of precordial pain over a period of five years before entry. There is no statement as to the duration of these attacks, but presumably they were longer than the usual attack of angina pectoris, since they required morphine for relief. Of importance, however, is the fact that the attacks were attended by palpitation and irregular heart action which are not characteristic of angina pectoris or coronary thrombosis as we usually encounter them. I should say that these attacks were due to paroxysmal rapid heart action, probably paroxysmal auricular fibrillation, and that this in turn induced angina pectoris. I am sure these attacks would have been given more space in the history if they had been due to coronary thrombosis.

Four years before her death she had a right hemi-

plegia, probably the result of a cerebral hemorrhage, since her blood pressure was found to be 260 at that time. However, if auricular fibrillation was present in paroxysms or constantly at that time this may have been due to embolism. The rapid complete recovery suggests this.

For two years before her death she showed gradually increasing signs of myocardial insufficiency characterized by dyspnea, orthopnea, weakness, increasing edema and finally massive generalized anasarca, in spite of measures usually adequate to control congestive heart failure.

The past history and family history reveal little of importance bearing on the present illness. It would be of interest to know what was displacing her liver—other than hepatic engorgement—at the time of the laparotomy eight years before entry. If this was merely a swollen, displaced liver or spleen it would indicate that her congestion was of much longer standing than the history indicates.

The physical examination shows the picture of extreme congestive heart failure. From its distribution there seems little doubt that the edema was almost entirely cardiac in origin. However, there may have been some superimposed nutritional edema. But we need no other explanation for the degree of her swelling than congestive heart failure. With this degree of failure one would expect rather pronounced cyanosis. Why it is not present, I cannot say. The eyeground changes represent a part of the general cardiovascular-renal disturbance. I have interpreted the slight engorgement of the chest veins as probably a part of the general congestion and not the result of local extraneous pressure on the superior vena cava or one of its branches.

From the single specimen reported one might consider the urinary findings as those of chronic nephritis with edema, but they are also consistent with a state of passive congestion in the kidneys. The absence of nitrogen retention in the blood makes me feel certain of this. Impairment of renal function, however, and perhaps malnutrition, has resulted in a blood protein that is below the threshold of edema. The positive guaiac test is probably due to congestion in the viscera. The electrocardiographic findings are consistent with hypertensive heart disease with perhaps some coronary involvement. A liver function test was apparently done to rule out cirrhosis.

X-rays of the chest show gross cardiac enlargement that is consistent with a long-standing process, aortic calcification and diffuse pulmonary vascular engorgement, indicating the presence of advanced left-sided heart failure as well as right-sided failure, of which there is so much evidence. Her response to treatment was evidently satis-

factory but she died on the tenth day after admission. Her condition, to be sure, required drastic methods, but there is some evidence now, as demonstrated by Dr. Schnitker at the Peter Bent Brigham Hospital, to show that such a rapid diuresis as occurred here may have its harmful effects. His idea, which is supported by some excellent experimental work, is that edema fluid of digitalized patients contains digitalis bodies, and as the fluid is withdrawn from the tissues and body cavities by diuresis to be excreted through the kidneys by way of the blood stream, there is an additional effect upon the heart which may produce digitalis intoxication. I mention this as a possibility here although no evidence is presented to suggest it.

Depending upon one's point of view it seems that this case can be regarded as one of essential hypertension with cardiac, renal and cerebral complications or as one of chronic nephritis without edema (until cardiac edema supervened) with attendant hypertension and its complications. I think the former is more likely. The immediate cause of death was probably massive or multiple pulmonary infarction, possibly coronary thrombosis. I favor the former because with the improvement in the circulation two factors come into play that favor pulmonary infarction: first, with the increased venous return to the heart, congestion in the lungs may increase, favoring intrapulmonary arterial thrombosis; secondly, the dislodging of a thrombus from the deeper veins of the peripheral circulation is likely to occur. A cerebral accident would not cause death so quickly or so silently unless it involved a vital area like the respiratory center. In the presence of long-standing hypertension, dissecting aortic aneurysm may be listed as a possibility, but there is no clinical evidence to support this diagnosis.

I would, therefore, list my diagnoses as follows: essential hypertension, hypertensive and coronary heart disease with marked cardiac enlargement, auricular fibrillation and congestive heart failure, cerebral hemorrhage (four years ago), chronic nephritis (small granular kidney), pulmonary infarction (terminal).

CLINICAL DIAGNOSES

Hypertensive and arteriosclerotic heart disease
Congestive heart failure
Auricular fibrillation

DR. GLENDY'S DIAGNOSES

Essential hypertension
Hypertensive and coronary heart disease with marked cardiac enlargement, auricular fibrillation and congestive heart failure

Cerebral hemorrhage (four years ago)
Chronic nephritis (small granular kidney)
Pulmonary infarction (terminal)

ANATOMIC DIAGNOSES

Cardiac hypertrophy, hypertensive type
Arteriosclerosis, aortic, coronary and cerebral
Chronic passive congestion
Anasarca
Cholelithiasis
Operative wound vaginal hysterectomy

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: The heart as was expected was found to be greatly hypertrophied, weighing 655 gm. Foci of calcification were present near the bases of both the aortic and mitral valves but they were too circumscribed to have interfered with function. The myocardium showed no significant amount of scarring and the coronaries though markedly calcified showed no significant narrowing.

I was much interested in the lungs at the time of autopsy since they seemed unusually congested and heavy. Cardiac patients very rarely, in my experience, die in an attack of cardiac asthma and for a time I was hopeful that this might be such a case. More careful examination showed, however, that the edema in this case was almost entirely interstitial, not intra-alveolar as it would be in cardiac asthma. Her years of bronchial asthma had left no trace such as chronic bronchitis or emphysema.

The other viscera showed little in gross except severe chronic passive congestion. The kidneys showed moderate arteriolar changes consistent with her hypertension. There was not enough destruction of renal parenchyma to have interfered with renal function.

The brain showed a definite old area of softening about a thrombosed vessel on the left, undoubtedly responsible for the right hemiplegia four years before. There was considerable diffuse degeneration of the white matter bilaterally which was also unquestionably a very chronic lesion. The cerebral vessel showed considerable sclerosis but no fresh thrombosis.

We are left, therefore, with no explanation for her sudden death in spite of a complete and thorough autopsy. Such sudden deaths are seen in patients with patent but sclerotic coronary arteries and are usually called anginal deaths. The findings in this patient are consistent with such a death, but we cannot prove it.

FREEDOM OF SPEECH WITHIN THE MEDICAL PROFESSION

THERE appears in this issue of the *Journal* a letter which characterizes the Group Health Association, Inc., of Washington, D. C., as "the opening wedge of socialized medicine in the United States" and suggests that the participation in the opening celebration of the association "by one of the Harvard faculty be referred to the Massachusetts Medical Society for whatever action it deems necessary."

As a citizen of the United States, our correspondent has a right to express his personal opinion of the association, to criticize Dr. Richard Cabot's opinion and to ask this *Journal* to publish his opinion. The *Journal*, however, cannot provide the publicity requested without remark-

ing that Dr. Cabot as a citizen of the United States has exactly the same rights. In this we believe our correspondent will agree. Yet, unless we misunderstand him, his letter suggests that as members of the medical profession his rights and Dr. Cabot's are not the same. The evidence against Dr. Cabot as given in the *Washington Herald-Times* of October 31 and submitted to this *Journal* follows:

Prediction that prepayment medical health insurance groups employing salaried doctors would spread throughout the United States was made last night by Evans Clark, of New York, director of the Filene Twentieth Century Fund, at a meeting of HOLC employes and officials of the Federal Home Loan Bank Board at the Mayflower.

The meeting was an inaugural celebration of the new clinic run by the Group Health Association, Inc., made up of employes of the HOLC, and backed, in part, by the Twentieth Century Fund.

* * *

Dr. Richard Cabot, professor of medicine at Harvard University's graduate medical school, described prepayment group health insurance as "better doctoring for less money."

He asserted that group medical practice was "100 times better than private practice, where modern, assembled diagnoses of several doctors' is often impossible."

He added that salaried doctors are more honest than private doctors who often were tempted to perform expensive operations which were unnecessary.

A doctor on a steady salary, sure of his income, is less likely to be tempted to perform expensive but unneeded medical services than a private doctor who has no certainty of income.

The charge is, then, that Dr. Cabot has expressed an opinion concerning the relative quality and cost of medical care provided by different types of medical service and therefore has acted so unethically that disciplinary action should be taken by the Massachusetts Medical Society.

Has not our correspondent in his letter implied a comparison between the relative quality and cost of medical care provided by different types of medical service which is not complimentary to the many physicians now participating in so-called state and institutional medicine?

It seems unlikely that the Massachusetts Medical Society has information that can prove one com-

parison just and the other unjust, and that thus warrants discriminative action

But possibly our correspondent has an ill-defined but definite feeling that physicians and medical organizations other than the American Medical Association should confine their discussion of medical practice and economics to remarks conforming to the ideas expressed by the official representatives of the American Medical Association. Possibly he has in the back of his mind the following report presented by the chairman of the Judicial Council to the House of Delegates of the American Medical Association in 1934

Whereas, The American Medical Association, including 100,000 physicians, is the only democratic body representing the organized profession of this country through delegates regularly elected through county and state medical societies, and

Whereas, Other medical organizations and groups, representing selected groups of specialists, have from time to time issued pronouncements of policies in the field of medical economics and medical practice, which do not represent the views of organized medicine and which purport to guide the medical profession and the public in the administration of medical affairs, and

Whereas, The House of Delegates of the American Medical Association has repeatedly condemned the issuing of such announcements and policies, which seriously embarrass the attempts of this organization to secure adequate care for the health of the American people and to protect the ideals of the medical profession, and

Whereas, The Board of Regents of the American College of Surgeons, assembled in Chicago on Sunday, June 10, promulgated a policy including a prepayment plan for medical care, restricted to so-called 'approved hospitals' to members of the staffs of such hospitals, and to physicians acceptable to such staffs, and

Whereas, This action of the Board of Regents of the American College of Surgeons has been spread to the people of the United States through the public press on the opening day of the annual session of this House of Delegates, therefore, be it

Resolved That the House of Delegates of the American Medical Association express its condemnation of such tactics and of this apparent attempt of the Board of Regents of the American College of Surgeons to dominate and control the nature of medical practice, and be it further

Resolved That the House of Delegates request the Board of Trustees of the American Medical Association and Judicial Council to ask the Board of Regents

of the American College of Surgeons, who are themselves members of the American Medical Association, to explain the reasons for their action and to justify the attempt by this small group within a specialistic organization to legislate for all the medical profession of this country, truly represented only by the American Medical Association

The resolution was adopted and carried unanimously

Our correspondent, knowing that reports made at medical meetings or presented in medical journals become the property of the public press, possibly thought these recommendations condemned free discussion of certain subjects by the profession

Perhaps then the charge is not that Dr Cabot expressed an opinion that was unjust but that he made a pronouncement of opinion within the field of medical economics and medical practice, which does not represent the views of the Massachusetts Medical Society. The case is then clear. The Massachusetts Medical Society may take action against Dr Cabot because his views are so widely held that they threaten the medical economics and practices supported by the Society and therefore they must be suppressed at all cost. Or the Society may decline to act because it is a democratic organization which respects and does not fear the rights of free speech and of minority opinion. In so doing it might remark that experience indicates that respect for these rights is essential for the successful operation of democratic institutions over any but very short periods of time.

SPOTTED FEVER

THE report¹ of two cases of probable spotted fever arising on Cape Cod is of the greatest public-health importance for the New England states. Until 1930 this disease was supposed to be limited to the Western states and the slopes of the Rocky Mountains. Largely through the studies of Rumreich, cases were then discovered in rural communities in Delaware, Maryland, Pennsylvania, North Carolina and the District of Columbia, and since that time studies carried on almost entirely by officers of the United States Public Health

Service have revealed isolated cases of the disease in most of the states on the Eastern seaboard

The cases at the Charles V Chapin Hospital in Providence unquestionably belonged to the Rickettsia group of diseases. Onset, symptoms and clinical course were characteristic, and the rash on one of the patients, still quite clearly apparent when seen by the writer of this editorial, was typical of this group of infections. Unfortunately, it is not possible to make an absolute differential diagnosis of diseases in this group without isolating the virus and studying its reactions and immunologic properties. Some information can be obtained from the Weil-Felix reaction, but in these cases, while the test definitely indicated Rickettsia infection, it was of limited differential value. Blood serums from the cases agglutinated the proteus bacillus OX 19 in dilutions high enough to be characteristic of typhus fever under ordinary circumstances. On the other hand, they also agglutinated the OXK type in high dilution, a phenomenon which usually occurs only in Tsutsugamushi fever but occasionally, though in relatively lower degree, in spotted fever. It is not safe to rely too strictly upon Weil-Felix differentiation, however, because high OX19 agglutinations have been found by Felix in the so-called "Sao Paulo" typhus, though this disease, both by immunologic reaction and tick transmission, is undoubtedly a form of spotted fever. The only method by which positive diagnosis of these cases within the Rickettsia group can be made—namely, isolation of the virus—unfortunately failed, but it is not always possible to obtain infection in guinea pigs injected with blood from such cases, even when the blood is taken at the height of the disease.

The probability that these were cases of spotted fever rather than typhus is assumed from the very definite history of tick bite in both instances. Moreover, neither rats nor fleas were detected in the environment of the patients, and there was no louse infestation.

The importance of these cases from the public-health point of view cannot be exaggerated. Ticks

are plentiful in southern Massachusetts, especially on Cape Cod, and these ticks—*Dermacentor variabilis*—have been shown by Dyer and his associates of the United States Public Health Service to be able to transmit the eastern type of Rocky Mountain spotted fever virus from the larva to the adult. Moreover, Badger, also of the Public Health Service, has traced a case of this variety directly to infected ticks of this species. Since *Dermacentor variabilis* is the ordinary American dog tick, and since it is not unlikely that dogs may remain, for a short time at least, carriers of the virus, the mechanism for endemic spotted fever transmission is well established in this region of Massachusetts.

In an attempt to clear up the situation, ticks and rodents from the neighborhood in East Brewster where the cases originated, were collected and sent to the laboratories of the Harvard Medical School. Unfortunately, the tick season was practically over by the time these collections were made, but a number of specimens both of larvae and adults were injected into guinea pigs. At the same time, transmission experiments were attempted from the brains of something over a dozen meadow and field mice caught in the same region. That meadow mice are susceptible to spotted fever virus has been known since 1934. So far, no definite results have been obtained from the laboratory inoculations, and in view of the large element of chance involved in such surveys, it is quite likely that no results will be obtained.

The fact remains, however, that two cases of unquestionable Rickettsia disease, probably spotted fever, were found to follow tick bite on Cape Cod, where no previous cases had been determined with certainty. The Massachusetts Department of Public Health has already taken an active interest in the situation, and unquestionably from now on there will be a rigid supervision of suspicious fevers of this kind. Machinery for immediate diagnosis and for epidemiologic and laboratory study is available.

CASE HISTORY No 53 PARTIAL SEPARATION
OF PLACENTA AT TERM

Mrs J K., a white primipara, aged twenty-nine years, at term, was awakened in bed by a sharp abdominal pain on April 6, 1935. The pain was extremely severe and was followed in ten minutes by a profuse hemorrhage which literally soaked the bed. She had had no previous staining. The patient was advised to enter the hospital.

The family history was negative. There was no history of tuberculosis, diabetes, malignancy or hemorrhagic disease. Her past history was negative. There had been no operations. Her catamenia had been normal with a twenty-eight-day cycle, the last one on June 26, 1934.

She was first seen on November 12, 1934, when five and a half months pregnant. She had had very little nausea and no vomiting. Except for constipation she had no complaints. Physical examination showed a well-nourished and developed woman. Her teeth were in good condition. The throat was negative except for a small amount of tonsillar tissue. The heart was not enlarged, there were no murmurs. The blood pressure was 118 systolic, 70 diastolic. The lungs were clear and resonant, there were no rales. The abdomen showed a palpable mass extending almost to the umbilicus. Neither kidney could be palpated. There was no abdominal spasm or tenderness. Her pelvic measurements were within normal limits. Vaginal examination revealed a nulliparous perineum, a soft but not patulous cervix and a uterus enlarged to the size of a five months' pregnancy. The outlet was ample. At the first visit, urinalysis showed no albumin, and subsequent urinalyses were normal. Her blood pressure at routine visits never went above 120 systolic, 80 diastolic.

On arrival at the hospital the patient was very pale and flowing profusely. The systolic blood pressure on arrival was 100 and dropped to 70 fifteen minutes later. The diastolic blood pressure was not recorded. The pulse rate was 60

but very weak. The membranes had ruptured. The uterus was definitely hard and tender. The fetal heart could be distinctly heard and was of good quality. The patient was conscious and having severe pain. She undoubtedly was in shock and suffering from acute hemorrhage. A compatible donor was obtained. A diagnosis of separated placenta was made because of the hardness and tenderness of the uterus. Intravenous glucose solution was started immediately while the operating room was being prepared. A classical cesarian section was done, and a male child was delivered who cried immediately. The placenta was removed and showed that one third of the placental area was the seat of separation. Several large clots were lying free in the uterine cavity and were removed. The uterus was of normal color and consistence and contracted well after the intravenous injection of pituitrin. There was no discoloration or other indication for removal of the uterus. Transfusion was started as soon as the baby was born, and 500 cc of blood were administered by the citrate method. Following the transfusion, the patient's color was good, the pulse was 80 per minute, and the blood pressure 100 systolic. The uterus continued to act well with normal flowing from below. The patient made an uneventful convalescence.

Comment. This case is a good example of the nontoxic and nontraumatic type of premature partial separation of the placenta. It differs from cases of completely separated placenta in that the amount of external bleeding is usually extremely large. No definite etiology could be discovered, and there was no warning of the impending disaster. Time is a most important element in these cases. In two hours from the onset of symptoms and one hour from entry into the hospital the patient has been operated on and transfused. A longer delay would undoubtedly have lost the child and would have endangered the life of the mother. This patient was a primipara not in labor, and the fetal heart was of good quality on admission. These factors added to the free bleeding made cesarian section the logical treatment. The Dublin method of rupturing the membranes, followed by packing the cervix and using a Spanish windlass, is applicable to cases of separated placenta when the baby is dead or not viable or the mother in profound shock. Prompt and repeated transfusions, if necessary, are essential. The question of removing the uterus in cases of completely separated placenta in which cesarian section is performed is answered at operation by the condition of the uterus. If this is mottled, soft and friable, it is wisest to do a hysterectomy.

ADDITIONAL APPLICATIONS FOR FELLOWSHIP

The following is a list of applications for fellowship which were received too late for publication prior to the meeting of the Board of Censors on November 4, 1937. It is the intention to present these names to the Council at the meeting on February 2, 1938, for final confirmation.

MISCELLANY

NEW MEDICAL DIRECTOR AT WOODSIDE COTTAGES

Dr Arthur H Ward, of Winchendon and Cambridge, will become medical director of Woodside Cottages, Framingham, on January 15, replacing Dr Franklin C. Southworth, who has resigned to take a position with the Buffalo City Hospital.

After graduating from Tufts College Medical School Dr Ward interned at the Cambridge Hospital. Following several years of general practice, he received his special training at the McLean Hospital and the New York Neurological and Psychiatric Institute, later serving as assistant to the late Dr Frank K. Hallock at Cromwell Hall for a period of six years.

Since 1933 Dr Ward has been in private practice with an office in Cambridge, at the same time conducting a small sanatorium for individual treatment of the psychoneuroses at Winchendon, and also serving on the staff of the Boston Dispensary. In addition to the State and county medical societies, he is a member of the American Psychiatric Association, the New England Society of Psychiatry and the Boston Society of Psychiatry and Neurology.

SOCIAL HYGIENE DAY

National Social Hygiene Day, the second observance of which has been set for February 2 by the American Social Hygiene Association, marks the high point in the year-round effort to gain popular interest and support for the activities of the health authorities and the medical profession in dealing with syphilis and gonorrhea. Interested official and voluntary agencies concentrate their efforts at

this time on giving the subject the widest possible publicity, by arranging for meetings of interested groups, press stories and comment, appropriate radio broadcasts, and the like.

The first National Social Hygiene Day, February 3, 1937, was an immediate success in accomplishing its purpose. It was marked by hundreds of meetings held throughout the country. More than a thousand newspaper clippings coming from all parts of the country testify to a uniformly favorable press.

Stamp Out Syphilis—Enemy of Youth is the slogan for the 1938 meetings. Particular emphasis will be laid on the control of syphilis among the twenty- to thirty year age group, in which more than half of all new infections occur.

Suggestions for meetings and practical community programs may be obtained from the American Social Hygiene Association, 50 West 50th Street, New York City. The association will be glad to supply interested persons and groups with materials, such as exhibits, films and literature.

PHYSICIANS ORGANIZATION IN THE COMMUNITY FUND CAMPAIGN

The organization of the physicians' group in Greater Boston's 1938 Community Fund Campaign has now been completed under the chairmanship of Dr Thomas R. Goethals. These workers total 107, and have been divided into ten groups each under a vice-chairman. The campaign opens Monday, January 24, and continues for a period of about two weeks, ending on February 8. The complete list of workers is as follows:

Thomas R. Goethals, chairman, (Mrs.) H. Bell, secretary.

Theodore L. Badger, vice-chairman. Committeemen: Marshall K. Bartlett, James M. Faulkner, Henry H. Faxon, John R. Frazee, Robert L. Goodale, J. Everts Greene, Ward I. Gregg, R. E. Mabrey, Michael E. Murray, Charles E. Short, Richard G. Whiting.

William B. Breed, vice-chairman. Committeemen: John W. Cass, Jr., Edwin F. Cave, A. W. Contratto, E. M. Daland, Hyman Green, A. D. Ludwig, G. Marks, Paul L. Norton, H. D. Stebbins, J. S. Sullman, Milton S. Thompson.

Joseph H. Burnett, vice-chairman. Committeemen: Charles H. Bradford, Virgil G. Casten, Edward J. Cotter, Allan L. Davis, Hugh C. Donahue, Henry E. Groden, Edward Harding, Edgar M. Holmes, Frederick J. Lynch, Abraham Myerson, Francis Rouillard.

Paul A. Chandler, vice-chairman. Committeemen: William G. Barrett, Richard Chute, Eugene C. Eppinger, John V. Leech, Alexander S. MacMillan, H. B. Nelson, John L. Newell, Fred A. Simmons, John W. Strieder.

Stewart H. Clifford, vice-chairman. Committeemen: Geoffrey Edsall, Henry E. Gallup, William T. Green, T. D. Jones, F. W. Marlow, Jr., Edward C. Vogt.

Trygve Gundersen, vice-chairman. Committeemen: William P. Beetham, Harry Blotner, Mahlon T. Easton, John M. Flynn, R. Earle Glendy, Allen P. Joslin, Alexander Marble, Leroy E. Parkins, Francis L. Weille.

Francis C. Neyton, vice-chairman. Committeemen: E. S. Emery, Jr., Marshall N. Fulton, Gerald Hoeffel, John P. Hubbard, H. E. Kennard, H. F. Newton, Henry N. Pratt, M. C. Sosman.

Robert S. Palmer, vice-chairman. Committeemen: Perry C. Baird, Allen G. Brailey, Earle M. Chapman, M. H. Clifford, Neil L. Crone, W. Garrey, A. Graviel Reed.

Harwood, C I Johnson, Lendon Snedeker, Moses J Stone, Claude E Welch, Vernon P Williams

Langdon Parsons, vice-chairman Committeemen F G Balch, Jr, Sidney C Graves, G Douglas Krumbhaar, Jacob Lerman, John P Monks, G S Speare, William B Stevens, George Sturgis, Somers H. Sturgis, C L Swan, Jr, Benjamin Tenney, Jr, Leon E. White, Jr

William T Salter, vice-chairman Committeemen Granville A Bennett, Austin M Brues, J T Edsall, Robert Morison, George van S Smith

RURAL COMMUNITY HOSPITALS

The acute shortage of doctors, hospitals and general medical facilities in many rural areas is brought out in a bulletin on 'Hospitals for Rural Communities' published by the United States Department of Agriculture. The study was made by the Bureau of Agricultural Economics Blanche Halbert, formerly of the bureau staff, is the author.

Noting that well-equipped rural hospitals will encourage doctors to enter country practice, the author says that the shortage of doctors in most small rural communities has become a serious problem. In a number of states where most of the people live in the country, there is only one doctor for every 1000 to 1500 persons. On the other hand, in other states which have a large percentage of urban population, there is one doctor to as few as 500 or 700 persons. The number of doctors in rural territory has been steadily decreasing. A great many small towns that had one or two doctors a few years ago have none at present.

As in the case of the doctors, the situation as to hospital facilities likewise places the rural communities at a great disadvantage. A survey made in 1934 showed that only about 1700 of the 3073 counties in the United States had any general hospital. This means that 1300 counties had no hospitals. By allowing two hospital beds per 1000 population and a distance of 50 miles from hospital centers, the study showed a need for 22,000 new hospital beds for the rural areas.

The hospital need is said to be greatest in the South where more than a million persons living in eight states had less than one hospital bed for every 2000 persons.

The bulletin discusses all the various considerations entering into the planning and building of a rural hospital—the needs of the community, the state laws that affect hospitals and hospital care, what it costs to build and operate a hospital, the financing, and the organization and administration. Numerous sketches show specific plans and specifications, and there are many illustrations of the building and work of rural hospitals in various parts of the country.

Before agreements are made for a new rural hospital, the author points out that some idea of the necessary size and expected occupancy should be obtained, for size affects the capital cost and occupancy affects the operating cost.

The expected occupancy of a hospital is dependent upon the proportion of beds to the population, the health education of the community and the attending physicians' habits of recommending hospital care.

The author concludes. A good rural hospital does more than provide for those in the community who actually need hospital care. If it is well equipped and well organized, it may attract physicians to the country district where it is located and it also may be the means of encouraging the doctors in the locality to stay in country practice. It enables these country doctors to see more patients and do better work. Its laboratories and facilities can be used for the diagnosis and treatment of all people.

It may become the center of the entire county health program."

A copy of the bulletin, No 1792 in the *Farmers' Bulletin* series, may be obtained from the Office of Information, United States Department of Agriculture, Washington, D C

BUCHANAN MEDAL AWARDED TO GENERAL RUSSELL

At the anniversary meeting of the Royal Society at Burlington House, London, on November 30, the Buchanan Medal was awarded to General Frederick F Russell, professor of preventive medicine and hygiene, Harvard Medical School.

After his resignation from the medical corps, U S Army, in 1920 he was appointed a director of the public health laboratory service of the International Health Board, a division of the Rockefeller Foundation, and from 1923 until September 1, 1935, was director of the board. During this period the board contributed generously toward the establishment of schools in hygiene in Europe, India and Singapore. It established a yellow fever unit in West Africa, large grants were made to the Health Section of the League of Nations, and the fellowships sponsored by the International Health Board were materially increased in number and extent. In view of these policies, public health activities throughout the world have greatly increased, and the Buchanan Medal was awarded to General Russell in recognition of his share in formulating and carrying out the projects.

CORRESPONDENCE

GROUP HEALTH ASSOCIATION, INCORPORATED

To the Editor Am enclosing a clipping from a recent issue of one of our local newspapers concerning the opening of Group Health Association, Inc, which I should term the opening wedge of socialized medicine in the United States, with the District of Columbia as the proving ground.

It is my sincere hope that this article be deserving of publication in the *New England Journal of Medicine*, or that the participation in the "celebration" above referred to by one of the Harvard faculty be referred to the Massachusetts Medical Society for whatever action it deems necessary.

A copy of this letter is being sent to Dr Cabot.

C A LALLY, M.D

3800 Cathedral Avenue, N W,
Washington, District of Columbia

UNWISE HASTE

To the Editor This morning's *Springfield Daily Republican* prints 'With his foot jamming, the accelerator against the floorboard and with a siren screeching a warning to motorists, State Trooper Edward J Haughey drove the cruising car which brought Ruth from Pittsfield to the hospital—138 miles—in two hours and forty five minutes.'

Ruth had swallowed a safety pin. So have other children. There is nothing unusual about such mishaps. And very, very rarely is there created thereby any dire emergency. Yet every now and then a case is built up, special

dispensation is granted—by whom one wonders—to break all speed laws, the press is given the news,—again by whom one wonders,—and a mad race is run across the State. Some day innocent but rightful users of the highway are going to be maimed, perhaps killed, in one of these mistakenly heroic rushes.

If there is lacking local talent to handle such mishaps, let the pace abroad be reasonable. It might be well also, before starting, to look near home for an expert. Albany is surely nearer Pittsfield than is Boston, and most likely has a doctor who could have removed Ruth's safety pin. Of course Springfield which was whizzed by is not Boston, but it has half a dozen surgeons who often extract odds and ends from throats, and do it skillfully without, may it be praised, a lot of newspaper notoriety.

ALLEN G. RICE, M.D.

33 School Street,
Springfield, Massachusetts

RECENT DEATHS

EASTMAN—ALEXANDER C. EASTMAN, M.D., formerly of Springfield, Mass., died in Florida, December 23. He was in his sixty third year.

A native of Framingham Center, he was a descendant of New England stock. He attended Worcester Academy, graduated from Amherst College in 1896 and received his degree from Harvard Medical School in 1900. The following year he entered general practice in Framingham. Later he moved to Southboro and from there to Springfield where he became a prominent specialist in children's diseases.

Dr Eastman had served as pediatrician at Mercy and Springfield hospitals, Springfield, president and medical director of the Baby Feeding Association, vice president of the Visiting Nurse Association and president of the New England Pediatric Society.

He was a former fellow of the American Medical Association and the Massachusetts Medical Society. Among his affiliations were memberships in the Springfield Academy of Medicine and the Springfield Medical Association.

His widow, two daughters and a son survive him.

GRANGER—KARLE H. GRANGER, M.D., of South Weymouth, a former fellow of the Massachusetts Medical Society, died December 28 at the Baker Memorial Hospital. He was in his sixty ninth year.

Born in Barnard, Vermont, he graduated from Johns Hopkins University and received his degree from Dartmouth Medical School in 1893.

Dr Granger was a member of the Masonic Order and the Wampatuck Lodge, I O O F.

His widow and a son survive him.

REPORTS OF MEETINGS

NEW ENGLAND OBSTETRICAL AND GYNECOLOGICAL SOCIETY

On December 1, the New England Obstetrical and Gynecological Society held its ninth annual meeting in Boston with headquarters at the University Club.

The morning was occupied by clinics at the Free Hospital for Women in Brookline, and the Boston City Hospital. In the afternoon, clinics were held at the Massachusetts Memorial Hospitals and the Carney Hospital.

The annual dinner took place at the University Club and was attended by the largest number of members which had ever assembled in the history of the organization. The speaker of the evening was Horace Z. Landon, who discussed Modern Germany from a Yankee Viewpoint."

A prize of \$250 which is awarded annually for the best article on either an obstetric or a gynecologic subject was presented to Dr Howard N. Simpson, of the Wesson Maternity Hospital, Springfield, Mass. The title of his essay was "The Role of Venous Pressure in Eclampsia."

BROOKFIELD MEDICAL CLUB

The 555th meeting of the Brookfield Medical Club was held at Ye Olde Tavern in West Brookfield, on Wednesday, December 15, with Dr George A. Moore, of Palmer, host, and Dr William Brady, of Holyoke, speaker, his subject being "The Acute Abdomen."

Two members, Dr Milman Pease, of Brookfield, and Dr Thomas O. Boyle, of North Brookfield, were taken into the club.

The next meeting will be held on January 19, with Dr Charles A. DeLand, of Warren, as host.

JOHN R. FOWLER, M.D., *Secretary*

NOTICES

SOUTH END MEDICAL CLUB

The next regular meeting of the South End Medical Club will be held at the headquarters of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston, on Tuesday, January 18, at 12 o'clock noon.

The speaker will be Dr Ariel W. George, his subject being "Value of X Ray in the Study of Gastrointestinal Lesions." Lantern slides will be used.

All physicians are cordially invited to attend.

JOHN B. HALL, M.D., *Secretary*

NEW ENGLAND HOSPITAL ASSOCIATION

The annual meeting of the New England Hospital Association will be held at the Hotel Statler, Boston, on March 10, 11 and 12.

The meeting will consist of papers on pertinent hospital administration, round table discussions and educational exhibits. Commercial exhibits will be presented in the ballroom of the Hotel Statler.

A. G. ENGELBACH, M.D., *Secretary*

BOSTON CITY HOSPITAL

The monthly clinicopathological conference will be held at the hospital on Wednesday, January 12, at 12 o'clock noon, in the Pathological Amphitheater.

JOSEPH E. HALLISEY, M.D.,
Secretary, Medical Staff

JOINT MEETING OF THE SUFFOLK DISTRICT MEDICAL SOCIETY AND THE BOSTON MEDICAL LIBRARY

There will be a joint meeting of the Suffolk District Medical Society and the Boston Medical Library at the Boston Medical Library, 8 Fenway, on Wednesday, January 19, at 8 15 p. m.

The "Principles and Proposals" will be discussed by the following: Dr Robert B. Osgood, Dr Frank H. Lahey,

Dr Channing Frothingham, Dr Elliott P Joslin, Dr Richard M Smith and Dr Roger I Lee.

JOHN P MONKS, M.D., *Secretary*,
Suffolk District Medical Society

JAMES M FAULKNER, M.D., *Secretary*,
Boston Medical Library

HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held in the Peter Bent Brigham Hospital amphitheater (Shattuck Street entrance), Tuesday, January 11, at 8 15 p m.

PROGRAM

Presentation of Cases

The History of the Development of Our Knowledge of Cardiovascular Disease. Dr Paul D White Illustrated with lantern slides

Medical students and physicians are cordially invited to attend

MARSHALL N FULTON, M.D., *Secretary*

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY, JANUARY 10

TUESDAY JANUARY 11

- *9 10 a m Boston Dispensary Review of Recent Literature on the Treatment of Malignant Diseases Dr William M Shedden
- 10 30 a m Massachusetts General Hospital Cardiac rounds
- *8 15 p m Harvard Medical Society Peter Bent Brigham Hospital amphitheater (Shattuck Street entrance)

WEDNESDAY JANUARY 12

- 8 a m Massachusetts General Hospital Grand rounds Orthopedic department
- *9 10 a m Boston Dispensary Sulfanilamide in the Treatment of Meningococcic Meningitis Dr Edwin H Place.
- *12 m Clinicopathological conference. Children's Hospital Amphitheater
- 12 m Boston City Hospital clinicopathological conference. Pathological amphitheater

THURSDAY JANUARY 13

- 8 30 a m 9 30 a m Exchange visit surgical and orthopedic staffs of the Peter Bent Brigham and Children's hospitals held this week at the Peter Bent Brigham Hospital
- 9 a m Massachusetts General Hospital Surgical grand rounds.
- *9 10 a m Boston Dispensary Bleeding from Peptic Ulcer Dr Maurice S Segal
- 9 15 a m Massachusetts General Hospital Neurological conference. Ether Dome
- 12 m Massachusetts General Hospital Clinicopathological conference.

FRIDAY JANUARY 14

- *9 10 a m Boston Dispensary Plasma Fibrinogen and the Sedimentation Test Dr Thomas H Ham
- 10 a m Massachusetts General Hospital Fracture rounds

SATURDAY JANUARY 15

- *9 10 a m Boston Dispensary Hospital Case Presentation Dr Heinz Magendantz
- *10 a m 12 m Staff rounds at the Peter Bent Brigham Hospital Conducted by Dr Henry A Christian

SUNDAY JANUARY 16

THE CHAIRMAN Our first paper is by Dr Francis P McCarthy His subject is "Physical Modalities in the Treatment of Discrete Superficial Skin Lesions"

PHYSICAL MODALITIES IN THE TREATMENT OF DISCRETE SUPERFICIAL SKIN LESIONS

FRANCIS P MCCARTHY, M.D *

BOSTON

THE use of physical therapeutic modalities in the eradication of superficial skin lesions, with particular reference to benign and malignant growths, has reached a stage where after several years we can more definitely evaluate their effects. Merely to consider the clinical phase of such lesions would be academic and unnecessary, but a knowledge of the histopathologic structure of a given lesion is essential to the intelligent use of physical therapy.

The treatment of many discrete skin lesions such as warts, various types of nevi and even malignant neoplasms is left to every sort of medical and lay practitioner, including the "beautician," the podiatrist, the electrolysis technician and even the barber. When one considers the difficulty of diagnosing many of these lesions even for the dermatologist, trained to interpret such conditions both clinically and histologically, it seems necessary to present a few fundamental facts in order to discourage the indiscriminate use of physical remedies. In discussing the treatment of discrete superficial lesions in the skin and the oral cavity, I shall attempt to indicate the proper modality called for by the clinical and histologic factors in the given case.

In general, it is desirable to note the location, size, color, consistence, depth and morphology of the lesion. If it is fairly large, and the diagnosis cannot be definitely determined, a small biopsy

specimen should be taken and examined histologically. If the lesions are multiple, excision and examination of a single lesion may be desirable. It is not an uncommon practice among the untrained to commence treatment without first determining the character of the growth.

As a pathologist I have been impressed by the frequent use of unnecessarily radical surgical procedures in the removal of simple benign lesions, such as the excision of a large V-shaped wedge of tissue from the lip or tongue for a simple retention mucous cyst. On the other hand, inadequate treatment of a rapidly growing squamous-cell carcinoma may favor metastases to the regional lymph nodes.

Among the physical agents used are the following:

Radium	Electrocautery
Roentgen rays	Actual cautery
Grenz rays	Electrolysis (galvanic current)
High frequency current	Carbon-dioxide snow
Cutting current	Ultraviolet rays
Electrodesiccation	
Electrocoagulation	

High-frequency current and carbon-dioxide snow I have found especially advantageous in the removal of benign and malignant superficial lesions. The use of radium and roentgen rays has been limited to deeper and more extensive lesions, which are not covered in this discussion.

The following tabulation indicates the wide variety of skin lesions which it is essential to recognize in order to apply the proper treatment.^{1 2}

Presented at the annual meeting of the Massachusetts Medical Society, Boston, June 1, 1937.

Professor of oral medicine, Tufts College Dental School.

Verrucae (many different types)	Chondrodermatitis nodularis chronica helices
Keratosis	Clavus
Senile	Fibroma
Leukoplakia	Granuloma pyogenicum
Kraurosis vulvae	Xanthoma
Miscellaneous	Xanthelasma palpebrarum
Nevi	Adenoma sebaceum
Vascular	Retention cysts (mucous)
Solid cellular	Sebaceous cysts
Keloids	Telangiectases
Tuberculides	Molluscum contagiosum
Cicatrices	Basal-cell epithelioma
Multiple benign cystic epitheliomas	Squamous-cell epithelioma
Dermatitis papillaris capillitii (acne keloid)	Melanocarcinoma

There are many other skin lesions in which physical therapeutic measures may be applied

I have selected from the list of cutaneous lesions several for discussion

VERRUCAE

Verruca Vulgaris The common wart occurs at all ages, but more often in the young, and tends to be autoinoculable. The histologic picture presents an entirely epithelial reaction—acanthosis and hyperkeratosis. In older people this lesion is often quite resistant to treatment, and carbon-dioxide snow with electrodesiccation offers the best form of therapy. In young children carbon-dioxide snow is the most desirable method of treatment, pressure is exerted for about twenty seconds, and the procedure is repeated two or three times, depending on the size and consistence of the lesion. Overtreatment is to be avoided, as it causes unnecessary scars.

Verruca Plantaris The plantar wart has become more frequent in recent years than formerly, especially in women, through the wearing of thin-soled shoes, it presents a difficult problem in therapy, especially if only palliative measures are adopted. While x-rays and radium are both extremely useful here, I prefer the electrodesiccating current, with novocain injected deeply under the keratotic central plug of tissue, and with the fractional method of treatment. In some cases a complete removal may be effected at one sitting, but discomfort may be experienced during the healing stage.

Verruca Acuminata This type of new growth may be small or may represent large conglomerate condylomatous lesions. Curettage under local anesthesia before use of high-frequency current is sometimes desirable. Venereal warts are most successfully treated by electrodesic-

cation, although both carbon dioxide snow and electrolysis give good results.

Miscellaneous Warts occur not infrequently on the eyelids, they are usually filiform, and a very slight desiccating current is normally sufficient to eradicate them without scars. Where the scalp is the site of the lesion, care should be exercised not to overtreat, as there is some danger of localized permanent alopecia, although this is a rare occurrence. Recurrences in the scalp are very frequent, and small lesions are readily overlooked. Probably the most obstinate type of wart is that on the bearded portion of the face. It is generally small and flat, or filiform. High-frequency current skillfully applied is usually effective, but scarring is the rule rather than the exception, and recurrences are common as a result of reinoculation from shaving.

KERATOSES

Keratotic lesions may be either primary or secondary, and include precancerous lesions. Clinical experience is essential for their recognition. The seborrheic type is quite common, it usually begins in middle life and involves the face and trunk. The lesions are brownish or almost black, greasy, soft and multiple. There is a marked hyperkeratosis of closely packed horny lamellae, and moderate to marked irregular acanthosis, with a distinct basal layer. There is a nevoid grouping of the epithelial cells, with horn cysts in the epidermis and inflammatory reactions of varying degrees in the upper corium. The lesions are readily removed by carbon-dioxide snow or light electrodesiccation, and no scarring should result. They do not tend toward malignancy, but occasionally give rise to the basal-cell type of lesion.

Keratosis Senilis This is one of the commoner types and occurs principally on the face and the backs of the hands in individuals beyond middle life. The lesion may be indistinguishable from the seborrheic type, but is usually harder and more deeply pigmented. It is serious in nature, as it tends toward malignancy of the squamous-cell type, and often shows an invading ulcerative process beneath the overlying hyperkeratotic and acanthotic epithelial one. Radical destruction is indicated, although a biopsy may be advisable in order to ascertain whether a carcinoma has developed. It is interesting to note that while a squamous-cell epithelioma arising from a lesion on the face above the mouth tends to be locally malignant, those on the lip or neck metastasize to the cervical lymph nodes, especially if they are growing rapidly.

Electrodesiccation in the keratotic stage is in most

cases sufficient, but if the lesion is ulcerated and shows definite induration and ulceration, or if malignancy is present, excision with the cutting current or surgical excision may be necessary. In the treatment of senile keratoses, the resultant scar should not be taken into consideration, for the lesions are often malignant and thorough treatment is indicated.

Figure 1 *Leukoplakia buccalis* (Grade 4)—*verrucous squamous-cell carcinoma*

*Leukoplakia*³ This common hyperkeratotic, acanthotic oral lesion, is graded in four groups, according to its clinical appearance and histopathology.

Grade I is characterized by the initial reaction of the mucous membrane to irritation, indicated by a red, granular, sharply defined and slightly sensitive area which soon becomes whitish gray. The microscopic picture at this stage shows an inflammatory reaction of the corium without definite epithelial proliferation.

Grade II is a very distinct lesion characterized by bluish-white patches or plaques without palpable induration, but sharply outlined from the normal mucosa. They are quadrangular or irregularly polygonal, and seem to be applied to the mucous membrane.

Grade III is very definite and is easily recognized at a glance, even by a layman. It presents a milk-white, pearly or silvery indurated plaque, either localized or covering large areas. The lesion tends to wrinkle, especially if it involves the buccal mucosa. Microscopically the classic picture of marked hyperkeratosis, with acanthosis and cellular reaction of the corium, is seen.

Grade IV is a still more pronounced keratotic lesion, which is indurated and leathery in appear-

ance and displays evidences of malignancy—early erosion, fissuring of the plaque or warty proliferation of the surface. This grade of leukoplakia should be treated as an incipient malignant neoplasm.

In the lesions of leukoplakia, the most striking histologic change occurs in the epithelial layer, especially the horny layer, which is markedly hypertrophied, in many cases the flattened, nucleated, hyperkeratotic epithelium extends clear up to the surface of the specimen. The rete cones are enlarged and broadened, and the malpighian layer is distinctly thickened. In the more advanced stages the hypertrophy of all the epithelial layers, especially the horny layer, is noticeable. Edema of the acanthotic cells may occur, in the early malignant stage the orderly arrangement of the malpighian layer is disturbed, with the formation of atypical cells, and numerous mitoses may be found.

Figure 2 *Leukoplakia buccalis* (Grade 4) Shows marked hyperkeratosis and acanthosis with increased vascularity and cellular infiltration of tunica propria

Underlying the corium is usually a fairly pronounced cellular infiltration, with separation of the collagen fibers and diminution of the elastic fibers.

Except for the preventive measures of removal of the irritating factor in the mouth, together with abstinence from tobacco, the treatment of leukoplakia is unsatisfactory. Where tobacco is a factor and the patient continues to use it, removal is usually followed by a recurrence. Having tried various methods, I have virtually abandoned radium and x-ray in favor of electrodesiccation and electrocoagulation by monopolar and bipolar high-

frequency current. I have not employed the actual cautery, but believe it to be equally effective. I feel that the use of radium for leukoplakia of the tongue associated with atrophic luetic glossitis is provocative of malignancy where the treatment has been given in small doses over a considerable period of time. Malignancy has developed in 2 of my cases following this type of treatment where the radium plaque in 5- or 10-mg doses was used for from twenty minutes to half an hour. Treatments over a period of months ultimately resulted in the development of verrucous carcinomatous lesions. It is advisable in this type of case to stop all smoking, to keep the patient under close supervision and to use monopolar or bipolar electrocoagulation in the destruction of any lesion that tends toward malignancy. Since it is in such cases that multiple malignancies of the tongue develop, great care should be exercised in their examination, and the patient should report every few months. The vast majority of leukoplakias require no treatment and the use of local irritating or caustic remedies is contraindicated, as there is a possibility of stimulating a malignant change.

Kraurosis Vulvae This lesion represents a type of hyperkeratotic lesion that tends toward malignancy more frequently than does leukoplakia buccalis. Destructive desiccation or bipolar coagulation is recommended, or surgical excision in pronounced cases.

Miscellaneous In the miscellaneous group of skin keratoses are those that follow the use of arsenic and are found on the soles and palms. They tend to develop into the squamous-cell type of malignancy, and are best removed by electrodesiccation. Keratoses following x-ray or radium burns often give rise to malignancy and are difficult to treat, due to the underlying fibrosis and avascular tissue, they are apt to ulcerate if destroyed.

NEVI

Birthmarks are quite common and of many varieties, and their differentiation requires considerable diagnostic skill. In describing their treatment it is desirable to point out the various types, with particular reference to the tendency of some of them to become malignant, and to emphasize the necessity of discretion and judgment. More than thirty types have been described, but for the sake of simplicity these may be divided into two broad groups, the vascular and the solid cellular.

Vascular Nevi These are common, particularly in infants and young children, and consist of four varieties—nevus araneus (spider nevus), nevus flammeus (port-wine mark), and two kinds of angioma, the so-called strawberry hemangioma and the cavernous hemangioma.

Nevus araneus is a very superficial hemangioma, showing dilated capillary vessels emanating from a dot-like center. Either the galvanic needle or the high-frequency current may be used, the central spot being touched very lightly with the point of the needle, as a result, the lesion shrivels without leaving a scar.

Port-wine birthmarks are best left alone, especially if they cover extensive areas. Carbon-dioxide snow may blanch them out to a certain degree, but it is very difficult to achieve a uniform blanching, and the mottled effect may in the end present a more objectionable cosmetic effect than the original lesion.

Figure 3 Cavernous hemangioma of tongue

Cavernous hemangiomas are composed of relatively large vessels lined with endothelium, they occur deep in the skin and subcutaneous tissue, and are best treated with radium or x-ray therapy, depending on their size. Carbon-dioxide snow is recommended for small, superficial lesions. With pressure applied for about twenty seconds for three or four times, the lesion gradually shrinks and disappears, leaving a thin, smooth scar. Electrodesiccation and coagulation have also been employed in the treatment of small lesions, but I have found the former method preferable, freezing produces a thrombosis of the vessels, associated with an acute inflammatory reaction and necrosis. Very satisfactory results are obtained with intervals of from two to four weeks between treatments. In superficial vascular nevi of the strawberry

type, pressure treatment, with the water-cooled ultraviolet lamp to produce vesiculation, is very effective, and is comparable in its results to carbon dioxide snow.

Solid Nevus or Moles. Pigmented nevus may be simple, brownish-pigmented lesions, definitely benign in structure and course, or deep black to bluish and dangerous in their potential tendency to malignancy. It is in this class of skin lesions that a

Figure 4 Melanocarcinoma arising from pigmented mole of arm (fatal case)

knowledge of the clinical and histopathological structure is essential in evaluating the proper physical modality.

The common mole is small, oval, smooth, slightly elevated and pale brownish, with or without the growth of hair, it cannot be considered potentially malignant in view of the many millions of seed moles in existence. However, even the most benign mole, if subject to traumatism over a period of years, may take on active growth tendencies and become a malignant neoplasm, with an early tendency to blood-stream metastases.

Blue-black moles are best left alone or removed by wide excision, as the underlying nevus cells may extend a considerable distance from the periphery of the lesion. If situated where chronic irritation may stimulate growth they are especially dangerous, as they frequently take on malignant tendencies with the production of one of the most rapidly growing neoplasms — melanocarcinoma.

MISCELLANEOUS

Keloids. Keloidal growths of tissue represent hypertrophy of the collagen fibers of the corium, and may be spontaneous, or may follow scars from previous trauma or surgical incision. They occur in naturally susceptible individuals, and may even follow simple therapeutic procedures such as the removal of verrucae by electrodesiccation. Negroes and dark-skinned Caucasians have a special tendency toward these lesions. Surgery and electrosurgical therapy are contraindicated, radium for small lesions and roentgen therapy for larger ones give the best results.

Tuberculides. Many of the smaller, more superficial tuberculides may be treated by electrodesiccation with good results, especially if the lesions are discrete and cover extensive areas. The sarcoid

Figure 5 Keloid showing interlacing collagen fibers

of Boeck, verrucous lesions and focal areas, and discoid lupus erythematosus lesions are amenable to the desiccating current. Carbon-dioxide snow also may be utilized in the treatment of lupus vulgaris nodules and in lupus erythematosus. One must not, however, fail to realize that internal medication with the arsenicals, gold compounds and bismuth is applied with beneficial results in cutaneous tuberculosis, and that physical modalities are merely adjuncts in the therapy of these lesions.

Dermatitis Papillaris Capillitii (Acne Keloid). This lesion, usually located at the nape of the neck,

may present a hard problem in therapy. I have found electrodesiccation, followed by radium or roentgen therapy, effective.

Granuloma Pyogenicum This lesion is made up of granulation tissue, richly vascular and very persistent. Electrodesiccation, followed by curettage and further desiccation, generally destroys the

Figure 6 Basal-cell epithelioma of upper lip

lesion, but unless the treatment is thorough a rapid recurrence is the rule.

Xanthoma and Xanthelasma Palpebrarum The smaller lesions of xanthoma tuberosum may be destroyed by electrodesiccation, and excellent results are also obtained by it in xanthelasma of the eyelids. With the latter it is desirable to use a very small spark, as the cells comprising the lesion are highly susceptible to the electrical current, and promptly melt away upon a very light application. It is better to use fractional treatments than a single treatment that may be too severe, as disfiguring scars may be produced.

Retention Cysts Mucous retention cysts of the lips and oral cavity are best treated by electrodesiccation. An initial incision with expression of the contents may be desirable in the larger cyst, followed by the insertion of the electrode and the application of sufficient current to destroy the epithelial lining. Small sebaceous cysts of the skin may be treated along similar lines, but the ideal treatment of the larger cysts is surgical resec-

Telangiectases The enlarged superficial veins in old scars secondary to radiodermatitis may be destroyed by electrodesiccation, but as these ve-

Figure 7 Cystic basal-cell epithelioma (eyelid)
vessels are compensating for the poor circulation in the cicatrix, ulceration may follow if the treatment is too drastic.

Figure 8 Squamous-cell epithelioma of cheek (Grade 1)

Molluscum Contagiosum These lesions represent invaginated dyskeratotic epithelium and are readily shelled out by the curette, desiccation may be applied to the base of the lesion

Basal-Cell Epithelioma The basal-cell tumor is the common malignant lesion of the face, it has a characteristic appearance and can usually be diagnosed clinically without a biopsy. It is locally malignant and does not metastasize to the regional lymph nodes, but a certain percentage of these tumors contain epithelium of the prickle-cell type, in which cases more radical treatment should be applied. I have found electrodesiccation or coagulation the ideal treatment for a large number of these cases, in place of radium and roentgen ray therapy. Often a combination of radiation and electrodesiccation is desirable, and the resulting scar is usually superficial and soft.

Squamous-Cell Epithelioma⁵ The method of choice in the treatment of this type of malignancy is based on each individual case, with special reference to the grade of malignancy, the size and location of the lesion, and the question of metastasis. In early and superficial lesions electrodesiccation or coagulation may be sufficient to destroy the lesion, but more often a combination of electrodesurgery and radiation therapy is required.

SUMMARY

The clinical diagnosis of superficial lesions of the skin and the oral cavity is essential to an intelligent application of the proper physical modality. A knowledge of the histopathology is desirable so as to enable one to "read" the lesion in terms of the actual cellular process. Too often inadequate or too radical procedures are applied in treatment, based on ignorance of the clinical and histologic picture, and occasionally a metastatic, neoplastic process is caused by crude therapeutic methods.

DISCUSSION

THE CHAIRMAN The discussion will be opened by Dr Austin W. Cheever.

DR. ALSTIN W. CHEEVER, Boston Dr. McCarthy does not leave me very much to say, for he has covered the subject very well indeed, however, there are one or two points that come to my mind. One is that I wish there were more control of beauticians. A little while ago, what I supposed was a mole on an eyelid turned out to be melanotic carcinoma. I wonder what would have happened if a beautician had been removing the blemish. With only a galvanic needle, and no radium or diathermy, he might have done irreparable harm.

I think each one has his favorite methods. Some of mine differ from Dr. McCarthy's, for instance, I prefer radium on keratoses and epitheliomas. On plantar warts I like the x-ray best of all. It does not always work, but it seems to have a good effect in about 80 per cent of all cases. It is not the slightest bit uncomfortable to the patient. If it does not work, then there are other things to be done.

I suspect that all the warts are related. Can you tell me whether that is so? Is the seborrheic wart in the same class as the others?

DR. MCCARTHY Pathologically it is

DR. CHEEVER It seems so clinically. We see the seborrheic type on back and face, the little pedunculated ones on the neck and in the axillae, and little flat abortive ones on the backs of the hands, all on the same patient.

I should like to stress the advantage of treating all the warts on the same individual and on other members of the family at the same time. In one family of eight, all have warts. I can persuade three or four of them to come in within a week or so of each other for treatment, but the rest will not do so. As a result I have seen each member of this family probably four or five times unnecessarily.

In nevus flammeus I did not hear Dr. McCarthy suggest ultraviolet rays, I think they are of some value. I agree with him that carbon-dioxide snow is likely to cause a very unpleasantly mottled scar, and x-ray and radium result, I believe, in one almost as bad.

The so-called strawberry mark should usually be treated less cruelly than is usually done. One doctor has said that radium is the best treatment but that it should be aimed at the wall and not at the skin, because such lesions almost always disappear spontaneously. During the World War I examined the skins of from 75,000 to 100,000 recruits. I did not see one strawberry mark among them, yet in any of our children's hospital outpatient departments we see a number of these marks indicative that most of them disappear spontaneously. Outside of this, I certainly agree with Dr. McCarthy.

I want to emphasize his statement that one should understand the pathology of these lesions before tampering with them, not necessarily the pathology of the identical lesion concerned, but certainly the pathology of that particular type of lesion.

THE CHAIRMAN It is now necessary to appoint a committee to nominate officers for next year. It is customary for the chair to name this committee, and I nominate Dr. Franklin P. Lowry and Dr. Herman A. Osgood.

Three years ago Dr. William Bierman came to us and gave us the result of his research work. He now has two more years of splendid work to his credit. He will talk to us on 'The Treatment of Gonorrhea in Women by Means of Systemic and Additional Pelvic Heating.'

may present a hard problem in therapy. I have found electrodesiccation, followed by radium or roentgen therapy, effective.

Granuloma Pyogenicum This lesion is made up of granulation tissue, richly vascular and very persistent. Electrodesiccation, followed by curettage and further desiccation, generally destroys the

Figure 8 Squamous-cell epithelioma of cheek (Grade 1)

amount of current energy flowing along each cable. If we find that there is an undue amount of current flowing to one thigh, for example, we increase the resistance in that portion of the circuit, so that the current energy going to the other thigh becomes equalized. After about three hours the thigh cuffs are shifted to the calves.

The vaginal electrode which we use is patterned after plaster casts which we have made of numerous adult vaginas. The metal electrodes which have been made from these plaster casts come in four sizes, varying from 7 to 11 cm in length. The metallic mass of the electrodes and the handles connected to them are channeled so as to permit the insertion of a thermometer.

The thermometer serves as our guide in determining the quantity of diathermy current which is to be applied. It is specially constructed so that, through prisms on either side, its mercury column is readily visible for a distance of several feet. This makes it possible to read the thermometer through the window of the cabinet. The markings on the thermometer are widely separated, with gradations indicating 0.2°F . That amount of diathermy current is permitted to flow which will heat the tissues to a temperature which, transmitted through the metal of the electrode to the thermometer, registers between 109 and 110°F (42.8 and 43.5°C).

The pelvic temperature is held elevated at this higher level while the systemic temperature is maintained at about 106°F (41.2°C). The determination of systemic temperature is made by means of thermometers inserted into the mouth and the axilla. Before starting pelvic heating we determine the relation between the temperatures in the mouth, axilla and rectum. This helps to indicate the systemic temperature as judged by the elevation in the rectum. When the rectal temperature is no longer available as a guide, owing to the distortion produced by the pelvic heating, the mouth temperature is used and is generally considered to be about 0.7°F below the rectal temperature.

The systemic temperature elevation is maintained for about twelve hours. During this time the patient receives fluids, either plain cold water or cold 0.6 per cent saline solution, in quantities as large as she desires. To minimize her discomfort she is given sedation, usually $1/200$ gr of hyoscine hydrobromide in combination with $1/6$ gr of morphine sulfate. If necessary, small doses of morphine are repeated.

In addition to observations of temperature, the general condition of the patient is noted continuously, as determined by the color of the face, rate and character of the pulse, and so forth. Close and continuous watchfulness is essential in order to avoid untoward effects.

The purpose of the higher temperatures in the pelvis is to achieve the quicker lethal influence on the gonococcus. At 106.7°F (41.5°C) Carpenter and his co-workers have shown that the various strains of the gonococcus will resist heating for periods varying from six to thirty hours. At 109.3°F (42.8°C) the killing time is cut to about one half. We recognize that in addition to the direct thermal injury there are immune factors which serve to produce the death of the diplococcus within its human host. It is our experience that this treatment may be applied at any stage of gonococcal infection. However, we prefer not to administer the treatment in the period two days prior to, during and two days after menstruation. If pregnancy be present, there exists the possibility of doing damage to the fetus because of the high pelvic temperature.

We have had the opportunity of treating 125 women by means of this technic. In all these the diagnosis was confirmed by the direct observations of the organism in the cervical or urethral secretion or in both. One hundred and seventeen of these (93 per cent) were freed of gonococci. In our first series, consisting of 67 women who received from five to six hours of general hyperpyrexia, during three and a half to four hours of which additional pelvic heating was administered, 62 were rendered gonococcus-free in an average of 2.3 treatments per patient. In our second series of 58 women who received twelve hours of hyperpyrexia, including from six to eight hours of additional pelvic heating, in 55 the gonococcus disappeared after an average of 1.4 treatments per patient.

The determination of the necessity for re-treatment is based upon the finding of the organisms in cervical or urethral discharges on the day following the treatment. If the stained smears are negative, further examinations are continued at daily intervals for several days. The necessity for re-treatment depends on thermal resistance of the organism responsible for the infection and upon the immunity of the patient.

Within a few days following adequate treatment, there is a subsidence or disappearance of the vaginal discharge. The cervical secretion becomes mucoid and clear, microscopically containing only scattered leukocytes instead of the pus clumps previously found. The urethral smear contains only scattered leukocytes in addition to many epithelial cells and Döderlein bacilli. In a few cases, superficial mucosal burns have caused a prolongation of the discharge, with the healing of the mucosal area within two or three weeks, the discharge disappears. In a few other cases, trichomonas vaginitis has caused a continuation of the discharge fol-

THE TREATMENT OF GONORRHEA IN WOMEN BY MEANS OF SYSTEMIC AND ADDITIONAL PELVIC HEATING

WILLIAM BIERMAN, M.D.,* AND EDWARD A. HOROWITZ, M.D.†

NEW YORK CITY

THE object of the technic which we employ to treat gonorrhea in women is the destruction of the gonococcus within its human host by thermal means. That this can be accomplished at temperatures which the human organism can withstand is amply proved by *in vitro* experiments, as well as by the clinical experience of other workers and of ourselves. Our technic differs from that described by others in that we apply higher temperatures (108 to 110°F, or 42.3 to 43.5° C) to the female pelvis while the systemic temperature is simultaneously held at a lower level (at about 106°F, or 41.2°C). This permits more effective heating in the region where the organism exists—when its ravages are localized to the organs within the pelvis.

To produce this systemic and differentially increased pelvic heating, we first elevate the temperature of the entire body. For this we have employed the short-wave currents alone, a horizontal photothermal cabinet placed over the patient as she lies in bed, and the hot-water bath. At present we use a combination of photothermal and short-wave heating.

Our cabinet contains twelve 60-watt carbon filament lamps arranged so that two, four or twelve may be switched on or off at one time. By means of overhead pulleys and a counterbalancing weight this cabinet is easily lowered or raised over the patient, as she lies on a mattress placed on a wooden table. The entire body except the head is covered by the cabinet.

The patient—who has been previously examined so as to determine that she is not suffering from any disease (aside from her infection) which would contraindicate the treatment—has been given an enema and a light breakfast by way of preparation. Her feet have been wrapped in cotton and her legs encased in cotton leggings to prevent the possibility of a burn. Except for these leggings and a bed sheet placed over her, the patient lies nude within the cabinet.

To speed the elevation of systemic temperature, the conversive heating energy of the short-wave current is utilized. Two condenser pads 30 by 40

cm each are placed under the table so that one lies parallel to the region of the upper back and the other parallel to the area of the mid-thighs. These pads are connected to a short-wave machine of the type usually employed for routine treatment purposes, which produces a current of 50,000 megacycles (6-meter wave length).

Within about two hours the systemic temperature becomes elevated to approximately 106°F (41.2°C). The auxiliary energy of the short-wave current is then dispensed with and the apparatus for additional pelvic heating is applied. If the patient has shown evidence of acute peritoneal inflammation, as indicated by the presence of fever, lower abdominal pain and tenderness, the application of local pelvic heating is deferred for three or four hours.

We have found that the most effective method of applying local heating is by means of diathermy. Short-wave energy administered by metal vaginal electrodes can be used for this purpose. Our first experience in the simultaneous systemic and higher pelvic heating was gained by the use of these currents.¹ However, it is our impression that it is possible to localize the heating effect produced by diathermy more accurately than we can by means of short-wave currents. With the latter the heating process must continue for a period of from six to eight hours, and when this has been done, we have observed occasional overheating of the structures on the inner sides of the thighs. To avoid such local overheating with its painful sequelae, we apply the dispersive diathermy electrodes as follows. A metal belt about 8 cm in width and made of flexible lead-tin composition metal (such as is ordinarily employed for the administration of diathermy treatments) is placed around the waist. Two similar metal cuffs are placed around each thigh. These three electrodes are connected to one terminal of a diathermy machine. The other terminal is connected directly to the vaginal electrode. To arrange for still further dispersion of the current we take a large metal electrode about 25 by 30 cm in size and place it on the back of the patient, so that it makes definite contact with the posterior portion of the metal belt placed around the waist. In the circuit of each of the electric cables going to the three dispersive electrodes we have a milliamperemeter and a variable resistance. The purpose of this arrangement is to indicate the

Presented at the annual meeting of the Massachusetts Medical Society, Boston, June 1, 1937.

*Attending physical therapist, Mount Sinai Hospital.

†Adjunct gynecologist, Beth Israel Hospital.

amount of current energy flowing along each cable. If we find that there is an undue amount of current flowing to one thigh, for example, we increase the resistance in that portion of the circuit, so that the current energy going to the other thigh becomes equalized. After about three hours the thigh cuffs are shifted to the calves.

The vaginal electrode which we use is patterned after plaster casts which we have made of numerous adult vaginas. The metal electrodes which have been made from these plaster casts come in four sizes, varying from 7 to 11 cm in length. The metallic mass of the electrodes and the handles connected to them are channeled so as to permit the insertion of a thermometer.

The thermometer serves as our guide in determining the quantity of diathermy current which is to be applied. It is specially constructed so that, through prisms on either side, its mercury column is readily visible for a distance of several feet. This makes it possible to read the thermometer through the window of the cabinet. The markings on the thermometer are widely separated, with graduations indicating 0.2°F . That amount of diathermy current is permitted to flow which will heat the tissues to a temperature which, transmitted through the metal of the electrode to the thermometer, registers between 109 and 110°F (42.8 and 43.5°C).

The pelvic temperature is held elevated at this higher level while the systemic temperature is maintained at about 106°F (41.2°C). The determination of systemic temperature is made by means of thermometers inserted into the mouth and the axilla. Before starting pelvic heating we determine the relation between the temperatures in the mouth, axilla and rectum. This helps to indicate the systemic temperature as judged by the elevation in the rectum. When the rectal temperature is no longer available as a guide, owing to the distortion produced by the pelvic heating, the mouth temperature is used and is generally considered to be about 0.7°F below the rectal temperature.

The systemic temperature elevation is maintained for about twelve hours. During this time the patient receives fluids, either plain cold water or cold 0.6 per cent saline solution, in quantities as large as she desires. To minimize her discomfort she is given sedation, usually 1/200 gr of hyoscine hydrobromide in combination with 1/6 gr of morphine sulfate. If necessary, small doses of morphine are repeated.

In addition to observations of temperature, the general condition of the patient is noted continuously, as determined by the color of the face, rate and character of the pulse, and so forth. Close and continuous watchfulness is essential in order to avoid untoward effects.

The purpose of the higher temperatures in the pelvis is to achieve the quicker lethal influence on the gonococcus. At 106.7°F (41.5°C) Carpenter and his co-workers have shown that the various strains of the gonococcus will resist heating for periods varying from six to thirty hours. At 109.3°F (42.8°C) the killing time is cut to about one half. We recognize that in addition to the direct thermal injury there are immune factors which serve to produce the death of the diplococcus within its human host. It is our experience that this treatment may be applied at any stage of gonococcal infection. However, we prefer not to administer the treatment in the period two days prior to, during and two days after menstruation. If pregnancy be present, there exists the possibility of doing damage to the fetus because of the high pelvic temperature.

We have had the opportunity of treating 125 women by means of this technic. In all these the diagnosis was confirmed by the direct observations of the organism in the cervical or urethral secretion or in both. One hundred and seventeen of these (93 per cent) were freed of gonococci. In our first series, consisting of 67 women who received from five to six hours of general hyperpyrexia, during three and a half to four hours of which additional pelvic heating was administered, 62 were rendered gonococcus-free in an average of 2.3 treatments per patient. In our second series of 58 women who received twelve hours of hyperpyrexia, including from six to eight hours of additional pelvic heating, in 55 the gonococcus disappeared after an average of 1.4 treatments per patient.

The determination of the necessity for re-treatment is based upon the finding of the organisms in cervical or urethral discharges on the day following the treatment. If the stained smears are negative, further examinations are continued at daily intervals for several days. The necessity for re-treatment depends on thermal resistance of the organism responsible for the infection and upon the immunity of the patient.

Within a few days following adequate treatment, there is a subsidence or disappearance of the vaginal discharge. The cervical secretion becomes mucoid and clear, microscopically containing only scattered leukocytes instead of the pus clumps previously found. The urethral smear contains only scattered leukocytes in addition to many epithelial cells and Döderlein bacilli. In a few cases, superficial mucosal burns have caused a prolongation of the discharge, with the healing of the mucosal area within two or three weeks, the discharge disappears. In a few other cases, trichomonas vaginitis has caused a continuation of the discharge fol-

lowing the disappearance of gonococci. This discharge ceases with the application of measures directed against the vaginitis.

About one third of the cases were complicated by salpingitis. In the acute or subacute salpingitis cases, pain usually disappears after the first treatment. We have observed that treatments may be instituted at any stage of gonococcal infection, even in the presence of acute salpingitis, associated with fever and pelvic peritonitis. Tubo-ovarian inflammatory masses, including those which are probably suppurative and associated with a rapid sedimentation time, respond satisfactorily to this type of treatment. There is first a diminution or disappearance of pain, and a return of the temperature to normal the day following the treatment. The temperature remains normal. Rapid sedimentation rates become slower.

Pelvic examination within a few days after treatment usually reveals a marked lessening of pelvic tenderness, but little change in the size of the adnexal masses. From seven to ten days after treatment there is usually an increased mobility of the uterus and some shrinkage of the inflammatory masses. After about two weeks following the treatment, the adnexal masses become much smaller.

The first menstrual period following treatment sometimes comes on before the expected time, and may be more profuse and of longer duration than usual. We have never observed a cessation of menstruation or the occurrence of menopause symptoms after treatment. A number of patients with chronic salpingitis associated with painful or prolonged menstruation noticed that menstruation became more normal and less painful following treatment.

Pregnancies and normal delivery have occurred in a number of patients whom we have previously treated for gonorrhea by this technic. In a number of patients with acute salpingitis at the time of treatment, insufflation by the Rubin method has subsequently demonstrated normal tubal patency.

The follow-up on most of these cases has been sufficiently prolonged (in some cases extending for a period of five years) to assure us that the disappearance of the gonococci has been permanent. We have relied upon frequently repeated smears,

especially those taken directly after the cessation of menstrual flow. In addition, in many cases we have made cultures. The danger of a woman's becoming reinfected by resumption of relations with the sex partner who originally infected her or with some other infected individual is always to be reckoned with. In 4 cases, after intervals of many months, during which repeated examinations failed to reveal the presence of abnormal discharge or of gonococci, a purulent discharge containing the organisms was again found. In each of these cases there was a definite history of new exposure to an infected partner.

SUMMARY

We have described the technic for the simultaneous production of systemic with still higher pelvic heating. Temperatures of 106°F (41.2°C) are achieved systemically, and of 109 to 110°F (42.8 to 43.5°C) within the region of the pelvis. This combined heating is maintained for a period of from six to eight hours. The interval of systemically elevated temperature is continued for a total of about twelve hours.

With this technic, as utilized in our last series of 58 cases, an average of but 14 treatments was found necessary to achieve the eradication of the gonococcus from its human host. With the disappearance of the organisms, associated symptoms disappear. Pelvic masses gradually subside. In our total series of 125 cases permanent disappearance of the organism was achieved in 117, or 93 per cent.

DR. FRANKLIN P. LOWRY: The committee nominates Dr. Frank E. Wheatley, of Boston, as chairman, and Dr. Herman A. Osgood, of Boston, as secretary.

Dr. Wheatley and Dr. Osgood were declared elected.

THE CHAIRMAN: I declare the meeting adjourned.

TRAUMATIC INJURY OF THE CONDYLOID PROCESS OF THE MANDIBLE

KURT H. THOMAS, D.M.D.*

BOSTON

TRAUMATIC injury of the condyloid process is not easily diagnosed and is often difficult to treat. It may occur in conjunction with a more obvious fracture of the body of the mandible, when it is frequently overlooked. Fortunately, fractures of the condyle often heal without special attention, particularly when prompt treatment by means of intermaxillary ligation and fixation of the jaw is given. There are exceptions, however. Untreated fractures complicated by dislocation may have permanent limitation of motion, and resultant discomfort during mastication. In edentulous jaws considerable shortening of the ramus and asymmetry of the face due to overriding of the fragments is liable to occur if correctly constructed splints are not used. In compound injury with fracture of the articular fossa, or in the presence of infection, ankylosis may result.

Traumatic injury to the condyloid process may be classified as follows:

- I Subluxation (unilateral or bilateral)
- II Dislocation without fracture (unilateral or bilateral)
 - a Forward.
 - b Backward.
 - c Upward.
- III Collum fracture (unilateral or bilateral)
 - 1 Overriding of fragments.
 - 2 Displacement of condyloid process.
 - a Forward.
 - b Medial.
 - c Lateral.
 - 3 Dislocation of the condyloid process
 - a Medial.
 - b Lateral.
- IV Traumatic ankylosis (unilateral or bilateral)

SUBLUXATION

Subluxation is often the result of minor trauma such as occurs when difficult tooth extractions are attempted, with application of undue force by means of forceps or elevators instead of the resection of a sufficient amount of alveolar bone to facilitate the operation. Careless use of the mouth gag during general anesthesia is another cause producing rupture of the joint ligaments or injury to the meniscus.

The patient complains of weakness of the joint felt when yawning or when undergoing prolonged operations in the dental chair. In some cases the condyle catches every time the jaw is opened wide, receding with a jumping motion. This is fre-

quently due to the rupture of the attachment of the external pterygoid muscle to the meniscus, which causes the latter to remain in place during the forward movement of the mandible instead of being pulled forward. The condyle therefore slides off its anterior margin, producing a sound when it strikes the articular eminence, this sound often becomes extremely annoying to the patient, as it occurs principally while eating and is audible to others. Subluxation may be unilateral but is generally bilateral.

The motion of the jaw should be limited by a dental appliance, or motion should be entirely prevented by means of intermaxillary ligation, so as to allow the ligaments to regain normalcy. This may require from three to six weeks. Intermaxillary fixation is to be preferred to the use of a four-tail bandage—first because it is invisible, and secondly because the patient is unable to remove it. Liquid diet should be prescribed.

DISLOCATION WITHOUT FRACTURE

The mandibular joint possesses motion not possible in any other joint, therefore trauma will not always markedly increase its limitations, and dislocation may occur frequently without the joint capsule's being ruptured and without the condyle's piercing it. Dislocation is frequently associated with fracture at the neck of the condyle or the ramus, and indeed many dislocations can occur only in conjunction with fracture. These will be discussed later. Dislocation of the mandible without fracture occurs bilaterally more often than unilaterally.

Forward dislocation. Though comparatively rare, this type of dislocation is more frequent than others. It occurs occasionally in newborn infants during delivery, especially in head presentations, but is seen more often in adults. It may be caused by a blow on the chin when the mouth is open, by opening the jaws too far when yawning or by the injudicious use of a gag under general anesthesia. When dislocated the condyle rests anterior to the articular eminence, where it is locked by tension of the temporal internal pterygoid and masseter muscles. The stylomandibular ligament, which is relaxed in ordinary forward motion, also becomes taut. The jaw remains in this position, as the combined effort of the muscles can no longer pull the head of the condyle back.

In acute forward dislocation the jaw is locked in

From the Brooks Hospital, Brookline.

Charles A. Br. Ketten Professor of Oral Pathology, Harvard Dental School.

a position that causes a so-called open bite. The chin is moved forward and down. Eating and talking is difficult, and there may be salivation and dribbling. In chronic dislocation the jaw slips back into its normal position more easily because the capsular and sphenostylomaxillary ligaments have been stretched. The patient, however, is well aware of the condition and fearful of repeated experiences, which are brought about from the slightest cause because of weakness in the articular attachments. Yawning or opening the mouth wide as during dental operations may bring on dislocation.

The symptoms, together with the prominence of the condyles, which can be easily palpated when the jaw is dislocated, aid in diagnosis. The latter may be verified by means of x-ray examination (Fig 1).

In acute dislocation, reduction by means of any force that makes the muscles and ligaments yield is inadvisable. It would cause further injury of the tissues, analogous to that which is often the cause of chronic dislocation. Instead, careful manipulation should be resorted to, reversing the process of dislocation. This is accomplished by opening the jaw wide, depressing the chin, and forcing the lower end of the ramus upward and backward. The head is thus made to glide over the eminence and back into the articular fossa; the jaws can then be closed. The use of general anesthesia facilitates the operation through relaxation of the muscles.

In order to prevent recurrence in acute dislocation, the motion of the mandible should be limited for a few weeks by applying bands to the teeth, to which are attached intermaxillary elastics or a silk cord to limit the opening to 1 cm.

In chronic dislocation the prognosis is rather poor. If not of too long standing, rest as described for subluxation may be of help. When dislocation occurs frequently and is accompanied by complete locking, permanent appliances as described for the acute type may be constructed.

Case 1 The patient, a 42-year-old female, complained of protrusion of the jaw. The earlier history was irrelevant. The present complaint had started six weeks previously, when she had had her remaining upper and lower teeth extracted. The mandible protruded and could not be moved as before. There had been no accidents or injury.

Clinical examination revealed prominent condyles on both sides of the face. The motion of the jaw was limited. Roentgen examination of the mandibular joint showed the condyle anterior to the eminentia articularis on both sides. The diagnosis was forward dislocation of the mandible (Fig 1).

Under ether anesthesia the condyles were manipulated to take their place in the mandibular fossae, when the true relation of the mandible to the maxilla was taken by plac-

ing wax plates previously prepared by the patient's dentist in the mouth and forcing the jaws into place. A temporary splint was improvised and held in place by a Barton bandage. Later the permanent splint constructed from the wax models was inserted and the jaw was held in

Figure 1 *Case 1* Forward dislocation of the mandible. The condyle is locked anteriorly to the articular eminence. A = fossa articularis B = position of condyle (C), anterior to articular eminence.

place by a four tail bandage for 6 weeks. The result was satisfactory, and the patient had upper and lower dentures made and could wear them without trouble.

Backward dislocation A blow directed backward against the chin may cause detachment at the posterior margin and forward displacement of the meniscus. The head of the condyle moves backward and upward, coming in contact with the glenoid fossa. This type of dislocation is fortunately of rare occurrence. I have seen it in the case of an automobile accident, the blow striking the chin without causing fracture of the body of the mandible. Hemorrhage which accumulates in the posterior part of the joint prevents the disk from returning to its normal position. In more serious trauma the bone may be crushed into the auditory canal, this may terminate in ankylosis (see below).

Such patients have the third molars in distal occlusion with open incisal bite (Fig 2). Motion of the jaw is interrupted when opening on account of interference from the displaced meniscus. In the case of fracture of the tympanic plate, bleeding from the ear is generally noticed and examination of the auditory canal may show obstruction.

Under ether anesthesia, with muscles well relaxed, the mandible is manipulated. Force is applied that tends to draw the condyle out of the articular fossa, this in turn may allow the meniscus to slide back into place. In order to keep the condyle out of the joint fossa until the tissue has recovered, the occlusal surface of the teeth should be raised in the upper jaw by inserting a rubber-plate

wedge made to fit over the posterior teeth. The jaw should not be immobilized, however, as motion is desirable to prevent fibrous ankylosis.

Case 2 The patient, a 30-year-old male, complained of inability to eat because he could not get his teeth to occlude, except the molars, and was unable to open his jaws wide on account of interference. He said that the surgeon who had treated him had asserted that under ether his jaw could be closed normally. The earlier history was irrelevant. The illness started after an automobile accident, when the maxilla was fractured on the right side, the fracture included the malar bone. The patient had since received treatment, and although the fracture had healed, his symptoms had not improved.

The clinical examination showed that the fractured part of the upper jaw had united too far lingually so that the teeth could not occlude normally. Furthermore, the in-

Figure 2. *Case 2 Backward dislocation. The condyle being pushed back and up against the glenoid fossa causes an open bite.*

cisors and premolars could not be brought into contact, as the last molar teeth on both sides came together and prevented closing of the bite. As this condition was the same on the left, where no fracture had occurred, it could not be attributed to the above mentioned malunion. Sometimes the patient could open his jaw wide, but at other times something interfered and he could open it but little. X-ray examination was advised, and a provisional diagnosis of backward dislocation of the mandible with displacement of the interarticular cartilage was made.

The x-ray report was essentially negative. There was no evidence of fracture or malunioned fracture in the region of the ramus or at the neck of the condyle.

With avertin and nitrous-oxide-oxygen anesthesia osteotomy was performed on the right maxilla, and a previously constructed splint was applied so as to assure healing in a normal position. The defective occlusion of the mandible was not improved thereby. The anesthesia was supplemented with ether to get complete muscular relaxation so that the jaw could be manipulated. It was found that by forcing down the ramus the mandible could be occluded normally. After a few attempts the jaw remained in normal position when closed, presumably because the meniscus had moved back into its normal place. Intermaxillary ligation was then used, by wiring the teeth to the splint in the upper jaw it was hoped that the incisors could not be forced back into the opened position.

A Barton bandage was applied to prevent pulling down of the side where the maxilla was fractured. After 5 weeks the wires were removed when it was found that the patient had no difficulty in closing his teeth normally and that the opening motion was no longer interfered with.

Upward dislocation This is extremely rare and may occur in conjunction with backward dislocation, or as a more serious condition when the condyle is forced through the glenoid fossa into the middle cerebral fossa. This is liable to happen where there are no posterior teeth to take up the force when a blow is directed to the anterior part of the mandible.

Reduction under general anesthesia should be followed by the application of a denture splint replacing the missing back teeth, the bite being opened at the same time. External drainage may be indicated. The splint should immobilize the jaw for four or five weeks. If ankylosis results, exercises with the purpose of forcefully opening the jaws are indicated. In extreme cases arthroplasty must finally be resorted to.

COLLUM FRACTURE OF CONDYLOID PROCESS

This is a common fracture, and probably occurs more frequently than statistics indicate, for in multiple fracture it is often overlooked. It is generally found at the lower part of the neck of the condyle (Fig 3), it frequently involves part of the ramus, extending in an oblique direction downward to the posterior border of the bone (Fig 4).

The fracture is caused by a blow on the chin, and is usually bilateral. It is often associated with fracture in the region of the symphysis. Unilateral fracture of the condyle may be associated with fracture of the mandible on the other side in the premolar or molar region. It may occur, however, as a single fracture when the blow is directed to the side of the face, for instance, in the region of the middle of the ramus. I have seen bilateral fractures caused by the following accidents: a girl of nine falling from a bicycle and striking her chin on the sidewalk, a rider falling when taking a hurdle, a flier landing his airplane, an amateur tree-chopper getting hit on the chin by the falling trunk, and several patients injured in automobile accidents. I have seen unilateral fractures in a boy who fell while roller skating, in a patient who received a lateral blow to the angle of the jaw, and in victims of automobile accidents. In one patient the collum fracture from a lateral blow was associated with fracture of the maxilla.

Collum Fracture with Overriding of Fragments

The overriding of the fragments is caused by muscular contraction. This is due to trismus resulting from collateral edema associated with the trauma. If most of the posterior teeth are present the condition is recognized by open bite in the incisor region. In jaws edentulous in the posterior part, it may be overlooked until after the swelling of the face has subsided, when we discover facial asymmetry, the angle of the jaw being higher and

the chin being moved toward the affected side. In cases where the jaw has united in such a position the patient complains of painful sensation in the joint and ear. This is due to pressure or friction caused by the condyle when moved in its abnormal relation.

Diagnosis is made by means of x-ray examinations of the joint from a lateral point of view and from an anteroposterior aspect. One or the other, or both, will show the deformity.

Treatment should be instituted as soon as possible after the accident. The fracture is reduced by means of manipulation under ether, followed by intermaxillary ligation if a full complement of teeth is present. In case of partially edentulous jaws a denture splint must be constructed before the reduction is attempted. This is inserted after satisfactory results have been obtained by manipulation, for the purpose of holding the jaws in proper relation while healing is taking place.

In malunion of long standing, discomfort in the joint may subside in time. If dentures are worn, these may have to be adjusted to the new maxillary relations, and this may also help to improve the condition. If pains are persistent, however, and radical surgical treatment is necessary, an osteotomy at the neck of the condyle may have to be performed, which when followed by fixation of the jaw in normal position will bring back normal relations. In complicated cases, osteoarthrotomy or arthroplasty may have to be resorted to.

Case 3 The patient, a 28 year-old female, complained of pain when moving the jaw, with pain in the ear and swelling of the face. The earlier history was irrelevant.

Figure 3 *Case 3* Collum fracture with overriding of fragment and shortening of the ramus due to muscular trismus. C = condyle F = fracture line

The condition was caused by an automobile accident 2 days before.

On clinical examination the posterior maxillary teeth on the left side were freely movable with a large section of the alveolar bone. There was crepitus on the left side when the jaw was opened, and pain upon pressure applied in front of the tragus of the ear. Provisional diagnoses

of fracture of the alveolar process of the maxilla and collum fracture of the left mandible were made. Roentgen examination was advised.

Intraoral films showed a fracture of the maxilla involving a fragment containing premolar and molar teeth. The mandible showed horizontal fracture through the neck of the condyle, with overriding of fragments and shortening of the ramus (Fig 3).

Under ether anesthesia a splint was placed in the upper jaw to hold the fractured parts in position. The ether anesthesia deepened and when the muscles of the jaw became relaxed the fracture of the condyle could be reduced by manipulation. Fixation was secured by intermaxillary ligation. Recovery was uneventful, and the splints and wires were removed after 6 weeks. Normal moulty was obtained after 10 days, during which the patient was advised to exercise the jaw systematically.

Case 4 This patient, a 24 year-old female, complained of a pain in the right mandibular joint and a crackling noise in the left one. She was unable to wear her dentures. She had been in an automobile accident 6 weeks previously, hitting the dashboard with the right side of the face (ramus). She had seen her family physician, who applied adhesive tape. Her teeth had all been extracted 7 months before, and she had had full dentures made 5 months before. These she had worn with comfort until the accident.

Clinical examination showed asymmetry of the face, the chin being drawn to the right, the median line of the lower denture was transposed about 1 cm to the right, and the teeth therefore did not occlude. Movement of the jaw was not interfered with, but a noise could be heard when the jaw was opened. There was no crepitus or other indication of ununited fracture.

The roentgen examination consisted of lateral and vertical exposures. The latter revealed a malunited fracture at the neck of the condyle of the mandible on the right. There was a slight outward displacement of the condyle, and because of overriding the ramus was shortened. The outline of the mandible and its location were asymmetrical.

The patient was advised to have a new set of dentures constructed by her dentist. These proved successful. The pain in the joint was relieved, but the facial appearance was not greatly improved.

Collum Fracture with Displacement of Condylar Process

Forward displacement This is the commonest type of displacement, since the external pterygoid muscle is attached to the neck of the condyle at the pterygoid pit and in case of fracture draws the neck of the condyle forward. The condition is recognized in a lateral x-ray of the mandibular joint (Fig 4).

Medial and lateral displacements Lateral displacement is more common. It is caused when the ramus is pressed upward on the inside of the condylar fragment, locking it into position by contraction of the masseter and internal pterygoid muscles. Lateral x-rays show the overriding, the anteroposterior view, on the other hand, shows the medial or lateral displacement of the condyle.

Reduction is accomplished by manipulation.

under avertin and ether anesthesia. The patient must be prepared for the operation so as to avoid postoperative vomiting. The jaws are immobilized for from five to six weeks by intermaxillary ligation or the use of splints. In cases of marked forward displacement, open reduction may be indicated. When the head of the condyle is moved into place it can generally be fixed by wiring the teeth, which is done by an assistant, the wound being protected by a piece of wet gauze. If this is not successful a galvanized nail may be placed anterior to the condylar fragment to hold the latter in place. It is allowed to project through the wound and is removed after a week or ten days.

Case 5 The patient, a 24-year-old male, complained of a fracture of the mandible, with bleeding from the chin, pain and inability to close the jaw. The previous history

Figure 4 *Case 5* Collum fracture bilateral with fracture at symphysis of mandible the x-ray shows a fracture of the condyle on the left with forward displacement of neck and overriding due to muscular contraction C = condyle F = fracture line

was irrelevant. The present illness started with an accident which occurred while the patient was cutting down a tree, the falling trunk struck him on the chin.

At the clinical examination there was pronounced swelling under the jaw and on the chin where there was a contusion of the skin. There was a slight swelling of both cheeks. The mandible had been displaced and there was crepitus in the anterior part and the region of the joints. The left superior central incisor was loose, as well as the right inferior central.

In the roentgen examination anteroposterior and lateral exposures were made. These showed a vertical fracture in the anterior portion of the lower jaw, close to the median line. Here an unerupted tooth was seen, which lay horizontally. The tooth did not seem fractured but the fracture line extended beyond it. The lateral view showed fractures at the necks of the condyles on the right and left sides. Both condyles appeared to be displaced anteriorly and there was overriding due to muscular contraction (Fig 4). Dental films of the upper teeth showed luxation of the left central incisor.

With premedication pentobarbital sodium (3 gr Nembutal), and gas-ether anesthesia the retained tooth

in the anterior part of the mandible was removed. The upper central tooth was extracted, as well as the lower one, which was found involved in the fracture. The jaw was placed in what appeared to be normal position and fixed with intermaxillary ligation. Roentgen examination after operation showed that manipulation of the fragments had not produced good results at the condyle. The patient was operated on again 2 days later. An external incision was made in front of the ear and extended at right angles along the zygomatic process. The condyles were exposed and forced into normal position. The patient was dismissed 11 days after operation. Healing was uneventful. Fifty-one days after the second operation the patient had normal union and could move his jaw well, occlusion was satisfactory.

Case 6 The patient, a 37-year-old male, complained of pain when moving the jaw and a swelling on the right side of the head. The previous history was irrelevant. The patient had a fall while taking a hurdle on horseback, injuring his left arm and shoulder, right ankle and face.

Clinical examination showed the region of the right condyle of the mandible to be tender on palpation, there

Figure 5 *Case 6* Collum fracture with lateral displacement C = condyle

were pain and crepitus when moving the jaw. A provisional diagnosis of fracture of the ramus was made.

Roentgen examination of the left arm and shoulder, thoracic cage, right leg and foot, and skull showed no evidence of fracture. The anteroposterior view of the head showed a fracture at the neck of the condyle, displaced laterally. There was considerable overriding, due to muscular contraction (Fig 5).

The fracture was reduced with ether anesthesia and the position retained by intermaxillary ligation. After 5 weeks the wires were removed and motion of the jaw was found to be normal except for slight muscular interference, which disappeared in a few days.

Collum Fracture with Dislocation of Condylar Process

Luxation fracture is not very common in the mandible, probably because of the free movement which is allowed the condyle in the joint. It oc-

curs as follows the bone fractures but does not separate, and on account of continuance of the traumatic action the condyle is then pressed out of the capsule either medially or laterally. Compound dislocation is rare.

Medial dislocation This is the common type of dislocation because of the action of the external pterygoid and the anatomic condition of the fossa articularis, which favors a medial dislocation rather than a lateral one. The meniscus generally remains in the fossa, while the condyle pierces the capsule. The cause may be a blow to the angle of the jaw, causing fracture at the neck without displacement, the continued force pressing the medially bent condyle out of the socket.

Case 7 The patient, a 9 year-old boy, had a swelling of the parotid region, and consulted his dentist on account of pain from an injured tooth. The dentist referred the patient for examination. The earlier history was irrele-

place by means of a hook while the ramus was pressed down by an assistant. The condyle could then be seen functioning in the socket as the jaw was moved. The fascia was brought together and held by catgut sutures, and the incision was closed with horsehair sutures. The teeth were fixed in occlusion by intermaxillary ligation. When the wires were removed after 23 days the jaw was stiff, but when the patient was seen 5 days later he had regained normal function.

Lateral dislocation This type is uncommon, as it is prevented by the very strong outer capsular ligament, and the protection afforded by the zygomatic arch. A case has been reported where the ramus fractured at the angle and the condyle was dislocated in a lateral and upward direction. In such cases compound fracture may occur.

The diagnosis is made by means of x ray examination. The anteroposterior view best shows the dislocation (Fig 6). The lateral view generally discloses the fracture line. There may be considerable swelling of the face. In the case reported above, this was mistaken for mumps and the patient received no treatment for two weeks.

Reduction is indicated even in cases of one or two weeks' standing, although the prognosis of an untreated dislocation is not bad, the condyle and ligaments having great power to adjust themselves to a new position, especially in children. If the fracture is incomplete, manipulation under general anesthesia may reduce the dislocation. As a rule, open reduction must be resorted to. The approach is through an incision along the lower border of the zygomatic arch, after which the condyle is located by blunt dissection. In lateral dislocation this presents no special difficulty, in median dislocation the external surface of the ramus should be exposed after detaching part of the masseter muscle. The condyle can then be located, taken hold of by means of an instrument with a half round, pointed hook, and pulled back into position while the ramus is pressed down. The wound is then closed and the jaw fixed by means of intermaxillary ligation or a splint. In spite of fixation, the retention of the meniscus and of the synovial membrane, if intact, prevents ankylosis. In case of destruction of the joint, however, ankylosis may result, especially in children. In such cases an arthroplasty may have to be performed later. When using intermaxillary ligation for retention it is important that the patient have no posterior edentulous condition on the affected side, because undue pressure on the condyle may cause resorptive processes during the period of fixation.

After four weeks the ligatures are removed. Although the result may be good, the patient may not have normal function at once. Exercises must be prescribed to limber up the jaw and to increase motility.

Figure 6 Case 7 Collum fracture with median dislocation C = condyle, F = fracture

vant. Two weeks previously the boy fell on the sidewalk and injured a front tooth. The next day a swelling appeared in front of the ear on the left side, and he was put to bed, as he was thought to have the mumps.

Clinical examination revealed a swelling in the zygomatic region, the patient could open his mouth only part way, and complained of pain when pressure was applied in the region of the condyle.

At roentgen examination the lateral view of the left side of the mandible showed an oblique fracture at the neck of the condyle without displacement. The anteroposterior view showed median dislocation of the head of the condyle (Fig 6).

Avertin anesthesia supplemented by ether was used. An incision was made over the zygomatic arch, and the ramus was exposed. The condyle was located and pulled into

TRAUMATIC ANKYLOSIS

Ankylosis of the jaw may follow traumatic injury, although it is more frequently caused by infectious arthritis, otitis media and osteomyelitis of the ramus. Orlow,¹ who wrote one of the most comprehensive articles on mandibular ankylosis, found trauma as the cause in 28 cases out of 100. In 23 of these cases the trauma was due to accidents such as a fall on the chin, a blow, or a fracture of the body of the jaw or base of the skull. In a few cases there was a compound fracture due to gunshot injury, and in 2 cases forceps delivery was the cause. We therefore find ankylosis resulting from a variety of traumatic injuries, the immediate causes, however, are interarticular hemorrhage, comminution of the joint and secondary infection. A case of fracture of the base of the skull complicated by otitis media and mastoiditis and followed by bony ankylosis and hyperostosis is reported below.

Ankylosis may be due to the formation of fibrous bands which firmly connect the condyle with the articular fossa. This condition frequently follows comminution of the interarticular meniscus or its destruction by secondary infection. It generally allows moderate hinge movement, but no forward and lateral motion. The patient is able to masticate moderately, particularly if he makes an effort to prevent complete ankylosis by means of exercises.

In other types of mandibular ankylosis there is bony union and therefore complete loss of function. This may be the end result of fibrous ankylosis, but may also occur directly, especially in trauma resulting in fracture or comminution of the bony part of the joint in the presence of infection. Extensive hyperostosis may result, with firm attachment to the base of the skull, or with union of the ramus to the zygomatic arch, often including the coronoid process.

The onset of ankylosis is not always promptly recognized because its development is gradual, and is often overshadowed by more noticeable symptoms such as swelling of the face, fractures of the body of the mandible or base of the skull and secondary infection of adjacent parts. Infants may have mandibular ankylosis, which during the period of nursing from the breast or the bottle may be overlooked, often until much later when solid food is ordered.

When ankylosis is complete there is generally little difficulty in establishing a diagnosis, as the patient's chief complaint is a long-standing history of inability to open the mouth. Fracture of the condyle of recent origin, which often prevents free motion, can easily enough be ruled out. Muscular trismus, however, sometimes produces complete locking of the jaw (pseudoankylosis),

and when it becomes chronic, as in cases of actinomycosis and myositis ossificans, may be mistaken for ankylosis vera. The commoner acute type of trismus of the masseter and internal pterygoid muscles is more easily differentiated. It is as a rule of very recent development, and is due to infection, particularly pericoronary infection around a partly erupted third molar. It is attended by pain, swelling at the angle of the jaw, painful deglutition and a rise in temperature. The x-ray easily discloses the condition. For the purpose of differential diagnosis it should also be remembered that the head of the condyle may be the seat of osteoma or chondroma. Such a case has been described by Ivy.²

In fibrous ankylosis the patient generally has slight motion, while in bony ankylosis motion is completely lost. The condition may occur bilaterally, but more frequently only one joint is affected. In cases of long standing the second joint may remain normal and retain its ability to function properly after operation on the affected side. If it is normal, the patient can push down the ramus slightly so as to create a small space between the molars, even if the other side is completely fixed.

In cases of ankylosis acquired very early in life the mandible remains markedly underdeveloped owing to lack of mastication. The chin recedes and the teeth are often crowded, so much so that the first permanent molars have insufficient room in which to erupt. The teeth also become carious and abscesses may form. Some patients are extremely undernourished, although it is remarkable how some of them, especially children, manage to push food into their mouths behind the last molars or through spaces created by the loss of deciduous teeth.

Ear deformities or the entire loss of the external ear are sometimes associated with childbirth trauma. I³ have reported a case of this type elsewhere. When treating such cases it must be remembered that the muscles are either underdeveloped or atrophied if ankylosis occurs late in life. This accounts for the disappointing fact that after an arthroplasty has been performed the patient cannot open his jaw very wide. Daily exercises are indicated in such cases, and often a dilator must be used for a long period of time in order to accomplish the desired result.

Roentgen examination often gives valuable information, although the result may be disappointing on account of anatomic conditions. In cases where hyperostosis is excessive and where ankylosis with the base of the skull or zygoma is involved, good roentgen demonstration of the deformity is especially difficult. It is nearly always necessary to take exposures from various angles, and the anteroposterior as well as lateral positions

are needed. Sometimes stereoscopic pictures are of value.

The treatment of ankylosis is surgical. Severing of the fibrous connections in the joint is seldom successful partly on account of the great depth of the condyle, which makes access difficult, and partly because this severance would hardly give permanent relief. Osteotomy at the neck of the condyle with arthroplasty often prevents reattachment, but only temporarily. The most satisfactory result is gained from osteoarthrotomy.

In performing an osteoarthrotomy a horizontal incision made over the zygomatic process and extended at right angles in front of the ear down to the tragus gives the desired exposure. The condyloid process is sectioned first generally at its attachment to the ramus, at about the height of the mandibular notch. The condyle is then excised. If there is considerable hyperostosis the chisel has to be used to separate the bone from the base of the skull or from the zygomatic arch. If the coronoid process is involved the osteotomy must be performed in the upper part of the ramus, with separation and excision of both the condyloid and coronoid processes.

Case 8 The patient, a 6-year-old boy, was referred for examination because his head had ached several times during the previous week, and because he had had pains in the stomach and vomiting. He was unable to open his jaw and could not eat properly. The previous history

Figure 7 *Case 8* Before operation the patient was not able to open his jaw.

was irrelevant. The boy had never been injured before or had previous trouble with his ears or jaw. The illness started 18 months previously, when he was knocked unconscious by an automobile. He was treated at a hospital for fracture of the left femur, which was somewhat comminuted; the leg was angulated and shortened. Soon after admission the patient developed an acute mastoiditis which was operated on. A definite fracture of the skull not visible in the x-ray picture, was discovered at operation. He was dismissed 2 months after the accident and was followed in the outpatient department, the last visit having been made 10 months previously.

The physical examination showed a thin, poorly developed and poorly nourished child, the skin was pale. He was unable to open his jaw. The right side was absolutely fixed, on the left side the teeth could be opened about 15 mm (Fig 7).

Roentgen examination showed a normal mandibular joint on the left, and bony ankylosis and hyperostosis of the condyle on the right (Fig 8).

Figure 8 *Case 8* Ankylosis and bony hyperostosis of the mandibular joint. Osteotomy was performed between the white dots and the bony mass was excised. C = enlarged condyle.

The diagnosis was bony ankylosis of the right mandibular joint. Osteoarthrotomy was advised.

With avertin and ether anesthesia an incision about 4 cm long was made along the zygomatic arch, and was extended by vertical incision in front of the tragus. After dissection of the skin flap the fascia was divided and the posterior attachment of the masseter muscle to the

Figure 9 *Case 8* After osteoarthrotomy the patient could open his jaw freely and masticate well.

zygomatic arch was severed. This brought into view the head of the condyle which was found to be greatly enlarged and about the size of a pigeon's egg. When the capsule was opened the articular surface was found solidly ankylosed to the glenoid fossa. The periosteum was

incised and the ramus was bared at the site of the attachment of the bony mass. Here an osteotomy was performed the chisel being forced in an oblique direction from the middle of the mandibular notch down to the posterior border of the ramus (Fig. 8). The jaw could then be forcibly opened to about 2.5 cm between the incisor teeth, after which it was freely movable. Next, the head of the condyle was excised, being separated from the base of the skull with a chisel. Its removal left a large space, which was partly filled with a piece of masseter muscle, turned over the cut-off part of the ramus and sutured to the internal pterygoid. A rubber drain was inserted to prevent hematoma. The fascia was sutured with catgut, and the skin with horsehair sutures.

The immediate postoperative condition was good, and the next day when the patient was examined it was found that he could open the jaw wide and without pain (Fig. 9). There was no facial paralysis. There was considerable local swelling about the wound but no infection. The drain was removed on the 2nd day. On the 4th day the patient developed a temperature of 103.5°F without pain in the jaw or other symptoms, and on the 6th day the temperature was 104.5°F, when a diagnosis of acute tonsillar tonsillitis was made by a consultant. He received treatment and the healing progressed uneventfully from then on. He was given chewing gum to exercise his muscles the 1st day after operation, and when dismissed was much improved physically, owing to the fact that he ate well and could masticate his food. At a re-examination 2 months later, it was reported that he was eating well and without any discomfort. He had very bad teeth because he had not been able to clean them or have them filled while his jaw was ankylosed, and was referred to a dental clinic for treatment.

SUMMARY

Traumatic injury of the condyloid process frequently results from minor trauma, such as occurs from application of undue force when extracting teeth, or from careless use of the mouth gag under general anesthesia. This often causes an injury involving the joint capsule, or the meniscus, or both, and produces a weakness of the joint that may be associated with an audible noise when eating.

More severe injury may produce dislocation of the mandibular joint. Forward, backward and

upward dislocations are distinguished. Diagnosis is made by clinical signs and x-ray examination. In forward dislocations the treatment is reduction, often under general anesthesia, to effect complete relaxation of the muscles, and the application of an appliance to limit motion for a few weeks. In case of backward and upward dislocations a rubber plate inserted over the teeth may be used to keep the condyle out of the joint fossa until the tissues have been restored to normal.

Fractures of the condyle occur more frequently than statistics indicate. In case of multiple fractures a collum fracture of the mandible may be easily overlooked. Careful x-ray examination from various positions is necessary for a complete diagnosis, as this fracture often is associated with forward, medial or lateral displacement of the neck of the condyle, or with medial or lateral dislocation of the head of the condyle.

The fracture can generally be reduced by manipulation under ether, after which intermaxillary ligation or the use of a splint is employed to immobilize the jaw. If there is marked displacement of the neck, or in cases of dislocation of the head of the condyle, open reduction may have to be resorted to in order to avoid malocclusion and associated masticatory difficulties. This is effected through an incision along the lower border of the zygomatic arch. The condyle can be pulled into position with a hook while the ramus is pressed down by an assistant.

In cases of traumatic destruction of the joint, or in untreated cases which have become ankylosed, osteoarthrotomy may be indicated.

IMMEDIATE SURGERY IN ACUTE CHOLECYSTITIS

HOWARD M. CLUTE, M.D.,* AND J. FRED LEMBRIGHT, M.D.†

BOSTON

IT IS apparent that surgical opinion regarding the delayed versus the immediate treatment of acute cholecystitis is gradually shifting toward the latter. The discussion has been revived from time to time by surgeons who disagree with the teachings of a previous generation that delayed operation is the treatment of choice, and who favor immediate surgery. Notable in this group are Miller,¹⁸ Graham,⁹ Eliason and McLaughlin,⁷ Zininger,²⁵ Stone and Owings,²¹ Mentzer,^{10, 17} Andrews³ and Heuer.¹¹ We agree that immediate operation is the ideal procedure, not only because our clinical experience with it has been highly satisfactory, but also and more especially because we believe that the underlying diseased process demands immediate attention.

The term "acute cholecystitis" implies an infectious process in the gall bladder, and is therefore misleading. Most students of the pathology of this disease now agree that obstruction of the cystic duct is the primary factor and that infection—when present—is almost always a secondary phenomenon depending on obstruction for its development. Usually the obstruction is caused by a stone (Baumgartner,⁴ Andrews,³ Judd,¹³ Hayes,¹⁰ Zininger,²⁵ Wilkie,²³ Lobingier¹⁵). In our experience a stone was impacted in the cystic duct in 28 of 29 cases. It is recognized, however, that obstruction may also occur as the result of edema arising from chemical irritation, for example, the regurgitation of pancreatic juice, or from edema caused by the lymphatics about the cystic duct, this lymphatic involvement being secondary to infection arising in the liver, the blood or the bowel. Allergy has recently been added by Alvarez¹ to the possible causes of edema in the region of the cystic duct. In general, however, it is true that in nearly all cases of acute cholecystitis the cystic duct is obstructed by a stone.

The anatomic relations of the cystic duct and the cystic artery, veins and lymphatics are such that obstruction to the duct inevitably involves to some degree the other structures at the root of the gall bladder. The cystic duct is naturally tortuous, and has numerous valves and papillary infoldings of mucous membrane in its lumen. We have repeatedly noticed that the artery leading to the gall bladder tends to take a short, straight course across the cystic duct to the gall bladder wall. During cholecystectomy, division of the cystic artery per-

mits the tortuous folds of the cystic duct to be elongated, and to be elevated from 0.5 to 1 cm. The veins and lymphatics leaving the gall bladder are extremely numerous, and are much more closely associated with the cystic duct than is the artery.

Impaction of a stone in the cystic duct produces swelling about the stone, which in turn affects the lymphatics, the veins and the artery leading to the gall bladder. The pressure on these structures will vary in degree according to the anatomic structure in the given case. Edema arising from pressure on the lymphatics and veins is probably the earliest result of an obstruction in the cystic duct. As this edema persists and increases, further interference with the blood supply occurs, so that in some cases branches of the cystic artery are shut off. Complete occlusion of the cystic artery rarely occurs (Lobingier¹⁵), but if it does, complete gangrene of the gall bladder results.

The development of edema, necrosis, gangrene or perforation in the wall of the gall bladder is therefore immediately dependent upon the extent to which the blood supply of the gall bladder is involved by the swelling around the cystic duct. Denton⁶ likened acute cholecystitis to a hemorrhagic infarct. The extent of the involvement of the gall-bladder wall varies according to whether large or small branches of the cystic artery are obstructed. Venous thrombosis is rare (Andrews³), the veins are usually dilated because of obstruction in the large venous plexus surrounding the juncture of the cystic and common ducts. Patches of gangrene and even perforation will occur as the edema, infarction and necrosis advance. Variations in the speed with which these changes occur after obstruction of the cystic duct appear will be pronounced, since the anatomic relations between the cystic duct, the artery and the veins are by no means constant.

There have been many studies of the bacteriology of acute cholecystitis, the outstanding ones in recent years being those made by Wilkie,²³ Denton,⁶ Feinblatt,⁵ Nickel and Judd,¹⁰ Branch,³ and most recently Andrews.² On one point all these investigators are in agreement, namely, that infection of the gall bladder is probably not the primary etiologic factor. Thus, Wilkie²³ showed that acute empyema followed intravenous injections of streptococci into animals when the cystic duct was obstructed, but failed to do so when it was patent. Nickel and Judd¹⁰ found pathogenic bacteria (streptococci) in the majority of cases of acute

Presented at the annual meeting of the New England Surgical Society, Providence, Rhode Island, October 1, 1937.

†Resident surgeon, Massachusetts Memorial Hospitals.

and subacute cholecystitis, while in the chronic cases, cultures taken from the gall-bladder contents were often sterile. Denton⁹ has failed to demonstrate lesions primarily of a bacterial nature in acute cholecystitis, and concludes that mechanical and circulatory factors account for the majority of gall-bladder lesions. Feinblatt⁸ holds that the role of infection as a cause of cholecystitis has been seriously overestimated. Branch⁵ believes that the organisms recovered from infected gall bladders do not necessarily constitute the primary etiologic factor in the development of acute lesions. The more recent studies of Andrews³ make it appear that the role of bacterial infection is indeed very minor. In quantitative studies he found as a rule no more bacteria in acutely inflamed gall bladders than in quiescent ones. Cultures taken from some of the severely damaged gall bladders were sterile. He states that in his experience empyema of the gall bladder has not been demonstrated by microscopic and bacteriologic studies. Denton⁹ and Feinblatt⁸ some years ago expressed similar ideas.

From the clinical point of view these findings are consistent with the course of many cases of acute cholecystitis. We have all operated on patients within forty-eight hours of the onset of pain and found gall bladders that appeared to be acutely inflamed, yet the fever, the white count, the general condition of the patient and the postoperative course were all consistent with a non-infectious lesion of the peritoneal cavity. In many respects the clinical picture of the early case of acute cholecystitis is identical with that of an early case of an ovarian cyst with twisted pedicle, and the course after operation in each case is much the same. Basically, the cause of these two conditions—an interference with the blood supply of an intraperitoneal viscus—is identical. In neither situation can the etiologic factor be considered a septic process.

If we agree that obstruction is first in the course of events in acute cholecystitis and is prerequisite to infection, it is obvious that immediate removal of the obstructed viscus before infection has occurred is the procedure of choice. The difficulties it presents are, first, the fact that in many cases there is a delay of several days before the surgeon is consulted, and secondly, that it is frequently impossible to decide from clinical study whether infection has been superimposed on obstruction.

Of the 29 patients with acute cholecystitis encountered since January 1, 1935, in private practice and in our service at the Massachusetts Memorial Hospitals, 1 was moribund on admission to the hospital, and died of perforation of the gall bladder and peritonitis. The other 28 patients were

operated on either early or late, and all recovered.

It is impossible to say exactly what constitutes an immediate operation for acute cholecystitis. In theory, it is best to operate on most cases within forty-eight hours of onset, but in practice we seldom have an opportunity to do so. The profession as a whole has not yet reached the position of recommending immediate surgery in this disease. In 12 of our 29 cases operation was performed four days or less from the time of onset. In all these patients the convalescence was easy and comfortable. High fevers and serious reactions were absent, and complications did not occur. These cases did not react postoperatively in any way like cases of abdominal infection. In 11 of these 12 cases the gall bladder was removed. In 1 patient, who was very short and extremely fat, the gall bladder was merely drained because of the technical difficulties of removal caused by her obesity.

In 16 cases, operation was performed from five to fifteen days after the acute attack. All these patients recovered, but several had a stormy convalescence, and some had serious postoperative complications. As a group they impressed us strongly as being much sicker and having a much more difficult time than did the patients who were operated on soon after onset. We removed the gall bladder in 13 of these 16 cases, in the other 3 it was drained because of perforation and abscess formation around it.

In our experience the delayed operation of cholecystectomy is definitely harder than the early one. In both there is much edema about the cystic duct and cystic artery, and their identification is difficult. In the early operation, however, the edema is not so fully organized and there is a less firm inflammatory thickening of these structures.

The postoperative course in our group of delayed operations was complicated in 2 cases by wound infections that required long stays in the hospital, and in 1 case by a subphrenic abscess that necessitated rib resection and drainage.

Perforation and abscess formation had occurred in 4 of our 28 operated cases (14 per cent). This figure approximates the figures for gangrene and perforation reported by other men in recent studies of larger numbers of cases. Kunath¹⁴ reports an incidence of 22 per cent and Heuer¹¹ one of 15.7 per cent. The high incidence of gangrene has not been sufficiently emphasized in the literature, and is a most important factor to be considered when deciding on the time for surgical treatment.

It had been our belief that stones in the common duct would rarely be found in acute cholecystitis,

since obstruction of the cystic duct was commonly present, and theoretically should prevent stones from entering. Among our operated patients, however, we found 5 who had stones in the common duct (18 per cent). Kunath¹⁴ reports that 7 per cent of his acute cases showed them. Only 1 of our stone cases showed jaundice, there were, however, 4 other patients who had jaundice but no stones in the common duct. This demonstrates once again that neither the presence nor the absence of jaundice is significant in regard to stones in the common duct.

Edema about the junction of the cystic and common ducts was repeatedly noted in this group of cases. Andrews³ believes that the slight jaundice seen in acute cases is caused by this inflammatory reaction and that this same phenomenon is responsible for the fever in certain cases of acute cholecystitis. He suggests that Charcot's intermittent fever may come from inflammatory obstruction of the common duct as well as from stones in it. In several of our patients who were operated on within forty-eight hours of the first pain, the gall bladder showed a tremendous increase in size, there was edema about an impacted stone at the junction of the cystic and common ducts, and there was a slight jaundice but no stone in the common duct. Immediate surgery in this type of case is safe, and will often rescue the patient from a long series of distressing complications.

We do not intend to enlarge upon the criteria by which to decide when to operate on late cases of acute cholecystitis. In the first place, we do not believe that specific data are available. All surgeons recognize fully that the pathology of this disease may be most deceptive, and that there is a very high percentage of error in correct diagnosis, particularly in the later stages. In general, our practice in late cases is to observe the patient for hours or days while giving him fluids and glucose. If we have evidence of spreading infection as suggested by a rising white-blood-cell count, a rising fever and a heightening pulse, we favor immediate drainage of the gall bladder. If it appears from our clinical impression and the above data that the infection is subsiding, we prefer delay and later operation.

SUMMARY

In this study of acute cholecystitis the advantages of the early operation have been emphasized. The basic lesion of acute cholecystitis is not infection, but obstruction to ducts and blood vessels, which produces edema, infarction and gangrene. The longer this process continues, the more chance there is for infection and its complications to develop. When the process can

be interrupted by immediate cholecystectomy, infection rarely occurs, complications are few, and the final results are very satisfactory.

DISCUSSION

DR WALTER G PHIPPEN, Salem. I wish to report a case of acute cholecystitis which was undoubtedly indirectly caused by trauma. A leather worker, aged forty two, was crushed on his right side between heavy rollers. The immediate result was a ruptured right ureter with extravasation of urine, which filled the retroperitoneal space. This was drained in an appropriate manner. About ten days later the patient developed all the signs and symptoms of an acute cholecystitis, and at operation the gall bladder was gangrenous. The cystic artery had apparently been obliterated by pressure of the indurated edematous mass in the retroperitoneal space. The gall bladder was removed. Later the right kidney was removed and the patient made an uneventful recovery. Undoubtedly the cholecystitis was the indirect result of the trauma.

DR FRANK H LAHEY, Boston. Early operation has the additional advantage of permitting the correct diagnosis to be made in cases of acute pancreatitis that would be overlooked if operation were delayed. It is impossible at times to distinguish between acute pancreatitis and acute cholecystitis. In the beginning of our experience we felt as Dr Clute did, that is, we tended to delay operation but the more we see these patients the more we lean toward early operation. I believe that the trend in that direction, as indicated in the literature, is the result of the growing conviction that acute cholecystitis is somewhat, though

not entirely, similar to acute appendicitis. When patients can stand operation and the risk is justifiable, early operation is better than delay.

DR LELAND S McKITTRICK, Boston. I should like to add a word concerning our experience with the six or eight diabetic patients we have seen who have come in with a stone impacted in the ampulla and a superimposed infection. Whereas we expect most of these conditions in non-diabetic patients to quiet down and permit more deliberate surgery, quite the opposite seems to be true in the patient with diabetes. With but one exception all this small group have gone on either to local perforation or to gangrene and empyema requiring drainage. In view of this we now feel that it is probably unwise to delay operation in such patients in the hope that an interval cholecystectomy may be done, but that it is probably better judgment to go ahead with operation as soon as the patient's carbohydrate metabolism and fluid balance have been brought to a point consistent with safe drainage of the gall bladder. It is apparently only the exceptional diabetic patient with an acute process who will be in good enough condition to permit removal of the gall bladder.

DR ARTHUR W ALLEN, Boston. The title of the paper, Immediate Surgery in Acute Cholecystitis, seems to imply the possibility of emergency operations in the middle of the night and at variable intervals during the disease. A patient with an acute gall bladder may arrive at the hospital within forty eight hours after the onset of pain, or four or five days after it. A great many patients arrive in such a distressing state, with dehydration, and

so forth, that an emergency operation is extremely dangerous. If such a precedent is followed, the mortality will be high. I am sure Dr Clute does not wish to imply immediate, but rather early, operation.

I believe that it is almost never necessary to operate on such patients in the middle of the night, as one might, for example, in a case of acute gangrenous appendix. If they are kept in the hospital for a few hours and their fluid balance is put in order, they are very much more likely to be in a relatively safe operable state than they would be if operated on as an emergency procedure. Furthermore, many patients whom we watch for a few hours and treat in a conservative manner are so much better by the next morning that I believe we can afford to delay and choose our own time for operation.

DR JOHN HOMANS, Boston. I have learned something from this paper. Having always believed that acute cholecystitis was dependent upon the presence of a stone impacted near the outlet of the gall bladder, it has seemed to me very unlikely that a stone should also be present in the common duct even if the patient is jaundiced. However, I did see a patient the other day in whom I found small stones caught in the cystic duct, and who showed a type of acute cholecystitis rather different from the ordinary in that case I now realize that the common duct might well have harbored a stone.

I was much interested to learn that the percentage of stones in the common duct in acute cholecystitis is so high. This is a factor which I have never before heard emphasized.

THE PRESENCE OF HEMOLYSINS IN ACUTE HEMOLYTIC ANEMIA

Preliminary Note

WILLIAM DAMESHEK, M.D.,* AND STEVEN O SCHWARTZ, M.D.†

BOSTON

WITHIN a period of four months we have observed 3 cases of severe hemolytic anemia characterized by acute onset, rapid development of profound anemia, fever, slight to moderate icterus and slight to moderate splenomegaly. In the first 2 cases, the blood picture showed high color index, increased mean corpuscular volume, macrocytosis and nucleated red blood cells. The resistance of the red cells to hypotonic salt solution was normal. In the third case, the blood picture corresponded to that commonly seen in congenital hemolytic icterus, namely, microcytosis, spherocytosis, increased erythrocyte thickness, and greatly increased fragility of the red cells to hypotonic salt solutions. Neither large daily doses of concentrated liver extract given parenterally in the first case nor repeated transfusions of blood in all

the cases were of any therapeutic value. Splenectomy was, however, followed by prompt and dramatic response, complete recovery occurring in all 3 cases.

The hemolytic character of the anemia in these cases is demonstrated by the following laboratory criteria: bilirubinemia, absence of bile in the urine and increased urinary urobilinogen, together with the signs of greatly increased regenerative activity on the part of the bone marrow as evidenced by polychromatophilia, reticulocytosis, nucleated red blood cells, the presence of immature polymorphonuclear cells and hyperplasia of the bone marrow on direct examination at biopsy.

In performing compatibility tests with the serum of L G (Case 2), it was noted that hemolysis of the red cells of prospective donors frequently occurred. Numerous experiments were then performed which demonstrated the presence in the patient's blood serum of a hemolytic factor which was active against cells of all four blood groups

*From the Hematology Laboratory and Medical Service, Beth Israel Hospital, Boston. Aided by a grant from the Charlton Fund, Tufts College Medical School.

†Read before the New England Pathological Society, November 18, 1937.

Associate Physician, Beth Israel Hospital.

†Charlton Fellow in Medicine.

normal control experiments being negative. On the appearance of the third case, tests for hemolysin again demonstrated the presence of a hemolytic factor active against the cells of all blood groups. The serum of the first case was then investigated and showed a similar, but weak, hemolytic activity.

METHODS

Fragility tests were done by the method of Daland and Worthley.¹ Urobilinogen was tested by the method of Wallace and Diamond.² The presence of hemolysins in the serum was determined by the following technique: 1 drop of fresh serum, 1 drop of a 5 per cent washed human red-cell suspension of the different isoagglutination blood groups and 1 drop of normal salt solution were mixed in 7 mm bore test tubes and allowed to stand at room temperature, or incubated at 37°C.*

Control observations using normal serums of various blood groups against the same red-cell suspensions were always made. In a few instances, the hemolytic titer of the serum was established by the following method: 0.5 cc. of 5 per cent suspensions of washed red cells, 0.5 cc. of 5 per cent guinea pig complement, 0.5 cc. of serum in successive dilutions, and 15 cc. of normal salt solution were mixed in 7 mm bore test tubes and incubated at 37°C for 1 hour.

Inactivation of serum was accomplished by heating in a water bath at 56°C for 30 minutes. Complement was obtained from guinea pigs by heart puncture; the blood was allowed to clot and the serum was pipetted off. The blood serums, which were kept at icebox temperature for varying lengths of time, were frequently tested for hemolytic activity.

The simple experiments for hemolytic activity were varied from time to time: the serum was kept in contact with its clot for several hours at 5°C, it was immediately chilled, it was mixed with human serum by the addition of 1 drop of homologous serum added to the hemolytic testing system.

CASE REPORTS

Case 1† H. L., an ice-company supervisor, aged 50, was admitted to the Waltham Hospital on May 19, 1937, complaining of increasing fatigue and weakness. The family history was entirely negative. There was a past history of peptic ulcer 6 years before, and intestinal grippe 4 months before. One month previous to admission the patient felt fatigue on exertion, which rapidly gave way to increasing weakness. Then followed edema of the legs, vomiting of bilious material and the passage of dark-colored urine. The patient's physician gave him large daily doses of liver extract parenterally, but when he failed to respond he was sent to the hospital. On admission he was obviously in desperate condition with extreme pallor, moderate icterus and orthopnea. There was no abnormality of the tongue, the edges of both the spleen and the liver could be felt three to four fingerbreadths below their respective costal margins, there was moderate pitting edema of the lower legs, the neurologic examination, including that of the vibration sense, was entirely negative.

*At the beginning of the studies in Cases 2 and 3 hemolysis took place almost immediately. Later it took place within an hour or more at room temperature, finally with the titer of hemolysins apparently diminishing hemolysis occurred only after incubation at 37°C.

†This patient was seen in consultation with Dr. Leo G. Blacklow to whom we are indebted for many courtesies.

The laboratory data are recorded in Table 1. In brief they showed marked anemia, apparently of the macrocytic variety, leukocytosis, evidences of marked regenerative activity of the marrow (polychromatophilia, reticulocytosis), nucleated red cells and polymorphonuclear leukocytosis, and the chemical findings of a hemolytic type of

icterus (bilirubinemia, lack of bile in the urine and much bile in the feces). Because of the patient's condition he was immediately transfused with 750 cc. of blood, and treatment with concentrated liver extract (Lederle) was continued in dosages of 3 cc. daily. The patient grew progressively worse, however, and even with two more transfusions and an increase in the dosage of liver extract to 6 cc. daily, he finally became almost moribund. Splenectomy was thought justified as an emergency procedure. Before the operation was performed, however, it was thought essential to do a sternal bone marrow biopsy to rule out the rare possibility of hemolytic anemia due to malignant neoplasm. The biopsy showed extreme normoblastic hyperplasia, a picture differing strikingly from that of the megaloblastic marrow of pernicious anemia. Following two transfusions of blood on May 31, splenectomy under spinal anesthesia was done by Dr. H. Quimby Gallupe. The patient made a most dramatic and uncomplicated recovery, the erythrocyte count rising at first by about 200,000 cells daily. The spleen weighed 500 gm., and there were several large infarcts. The sections showed extreme congestion, extensive hemorrhages, thrombosis of veins and capillaries, and hemosiderosis, but no apparent proliferation of reticuloendothelial cells. In September, the patient presented the typical features of an attack of gallstone colic. In November, about 5 months after splenectomy, he was in excellent condition and ready to resume his occupation. The question of hemolytic activity of the serum was not investigated in this patient until more than 3 months after splenectomy, at which time a weak hemolysin was demonstrated.

Case 2‡ L. G., a 38-year-old Italian American housewife, was admitted to the Cambridge Hospital on July

‡We are indebted to the visiting physicians of the Cambridge Hospital for the opportunity of studying this case.

17, 1937, complaining of increasing weakness. The family history was essentially negative. In 1934 cholecystectomy had been performed at another hospital for cholecystitis and cholelithiasis. At that time evidence of slight anemia was discovered. The patient was followed in the outpatient department of this hospital, where diagnoses of secondary anemia, cause unknown, and of hypothyroidism were made. Three weeks before entrance to the Cambridge Hospital she began to complain of weakness, which grew rapidly worse, in turn she developed dyspnea, palpitation and increasing pallor, and passed dark-colored urine. Examination on admission showed marked pallor with moderate icterus, a normal appearing tongue, a large spleen extending three or four fingerbreadths below the left costal margin, and a negative neurologic examination. The laboratory data are recorded in Table 2. Except for the presence of a normal or

to drop. On August 31 it was thought desirable to give parenterally 3 cc. of liver extract (Lilly concentrated) daily and iron in the form of ferrous sulfate, 1 gm. daily. Recovery continued uneventfully and on November 17, more than 3 months after splenectomy, the patient was in excellent physical condition and with normal blood findings.

In testing the patient's serum against the blood cells of prospective donors, it was noted that hemolysis frequently occurred. This was the occasion for testing the serum for hemolytic activity. A large number of experiments were performed as outlined above. These demonstrated in the serum a hemolytic factor which was active against red cells of all the blood groups, although in different degrees and with much individual variation (Table 4). Definite evidence for the presence of an autohemolysin was not demonstrated by the methods outlined above, but

somewhat diminished leukocyte count, the blood findings were almost identical with those of Case 1, and the urinary and blood chemical findings were those of a hemolytic type of icterus.

The patient was given two 3 cc. doses of liver extract (Lilly) intramuscularly, but showed no evidence of response. A bone marrow biopsy revealed intense normoblastic hyperplasia without evidence of pernicious anemia. On July 29 the patient was transferred to the Beth Israel Hospital, where she was given four transfusions of blood in 5 days without definite effect on the blood picture or the clinical status. The hemoglobin ranged between 20 and 30 per cent, and the erythrocyte count between 970,000 and 1,280,000. Splenectomy was therefore performed under spinal and cyclopropane anesthesia on August 4, the patient receiving 1200 cc. of blood during the day. There was an almost immediate and dramatic recovery, although the postoperative course was complicated by consolidation of the left lower lung. Two more transfusions of blood were given when the blood picture showed some tendency

when the serum was allowed to remain in the icebox in contact with its clot for 48 hours there was evidence of some hemolysis.

The spleen weighed 500 gm. It was characterized microscopically by relative diminution in size of the Malpighian corpuscles, with marked increase in cellularity of the pulp and the presence of many large irregular cells and occasional giant cells with multiple nuclei (reticuloendothelial hyperplasia). Hemosiderin was greatly increased, and there was definite evidence of erythrophagocytosis. A study of impression preparations of the spleen gave evidence of myeloid activity, with many myelocytes and nucleated red cells. Extracts of the spleen, which are now being further investigated, showed definite hemolytic activity.

Case 3 G. C., a 44-year-old, married, Jewish housewife, with a negative family and past history, was admitted to the Beth Israel Hospital on August 27, 1937, complaining of weakness. She had been well until 5 days previously, when she had developed fatigue and malaise. On the

next day, pallor and fever had been noted, 2 days before admission she had become prostrated. She walked into the hospital ward, with assistance, but a few hours later was semimoribund with an extremely rapid pulse, a temperature of 103°F and dyspnea. There was marked pallor, and moderate icterus. The tongue was normal, neither the liver nor spleen could be felt, the neurologic

tracts of the spleen, which are now being further investigated, showed definite hemolytic activity.

In this patient's serum a strong hemolytic factor was found which corresponded closely in its reactions to that of Case 2. Hemolysis was induced with cells of all blood groups (Table 4), and in addition an autohemolysis was demonstrated. Upon the addition of 1 drop of homologous

examination was negative. The blood (Table 3) showed marked anemia, with polymorphonuclear leukocytosis and many normoblasts. The striking features of the blood picture were large numbers of very thick looking microcytes (spherocytes). The fragility test was grossly abnormal, hemolysis began in a 0.72 per cent salt solution and was complete in a 0.44 per cent solution. The features of a hemolytic type of icterus were present. Seventeen hundred cc of blood was given during the course of the day. The patient failed to respond, and indeed became worse. A severe transfusion reaction developed with the passage of large amounts of urine containing hemoglobin and with an increase in icterus. She was transfused again, however, on the following day, but since there was no change, either clinically or hematologically, splenectomy was performed under ethylene-ether anesthesia. There was immediate clinical response, with quick loss of the previous toxic appearance, a diminution in icterus and a fall in temperature. Several transfusions were given postoperatively, on two occasions it was noted that icterus became increased after transfusion. Convalescence was rather slow and was characterized by slight fever, continued anemia and many nucleated red cells in the peripheral blood. Because of the possibility that a depletion of maturation and other blood forming substances might be occurring, 3 cc. of parenteral liver extract (Lilly, concentrated) and 1 gm. of ferrous sulfate were given daily beginning September 12. Convalescence occurred rapidly and the patient was discharged October 10. More than a month later (November 17), although she seemed clinically well, there was slight anemia and leukocytosis.

The spleen, which had been adherent to the diaphragm and therefore not palpable, weighed 360 gm and microscopically showed extreme congestion of the sinusoids, without hemosiderosis and without evidence of erythrophagocytosis. The splenic corpuscles were well marked. Ex-

amination of the human serum to the hemolytic test system described above, hemolysis was definitely inhibited.

With continued improvement after splenectomy, the hemolytic factor gradually became diminished, the spherocytes gradually disappeared and the fragility test finally became normal.

SUMMARY OF CASES

All the patients became acutely ill, with weakness as the outstanding symptom. In Case 3 the

Table 4 *Summary of Tests for Hemolytic Activity of Suspected Serums*

course was a precipitate one. Anemia developed rapidly and was associated with moderate icterus. The spleen was readily felt in the first 2 cases. Since pernicious anemia was the initial diagnosis in those cases, it was of interest to note the normal appearance of the tongue, the absence of neuro-

logic phenomena and the presence of free hydrochloric acid in the gastric juice. The blood picture was similar in the first 2 cases, being characterized by the presence of polychromatophilic macrocytes and an increase in the mean corpuscular volume, but by a normal, average red-cell diameter. Microcytosis was not striking, and the fragility test was normal. In the third case, spherocytosis (the presence of thick microcytes) was outstanding and was associated with a grossly abnormal fragility test. The jaundice was of the hemolytic variety with increased bilirubin of the indirect variety, acholic urine and increase in urinary urobilinogen.

In none of the cases were transfusions of any benefit. In fact on several occasions the reverse was true, definite evidence of increased blood breakdown occurring after transfusion. An adequate trial with large doses of parenteral liver extract in Case 1 failed to show any therapeutic results. Splenectomy performed as an emergency measure, with the patient in each case semimoribund, produced immediate therapeutic effect.

Experiments for hemolytic activity of the serums in these cases demonstrated the following (Table 5) pronounced hemolytic activity against cells of

Table 5 *Summary of Characteristics of Hemolytic Activity of Serums (Cases 2 and 3)*

STATE OF SERUM	BLOOD GROUPS OF RED CELLS TESTED			
	AB	A	B	O
Fresh serum	H	H	H	H
Fresh serum—after incubation with normal human serum	O	O	O	O
Fresh serum—after standing at 5° C for 15 hours	H+	H+	H-	H-
Fresh serum—after prolonged standing at 5° C	H-	H-	H-	H-
Heated serum—56° C for 1 hour	O	O	O	O
Heated serum—after addition of guinea pig complement	H	H	H	H

In all experiments 1 drop of serum, 1 drop of normal salt solution and 1 drop of a 5% suspension of red cells were used.

H=hemolysis

O=no hemolysis

H+=hemolysis more marked than with fresh serum

H-=hemolysis less marked than with fresh serum and gradually diminishing

all blood groups, including those of Group O. definite evidence of autohemolysis in Case 3, inactivation of hemolysis by heating the serum to 56°C, with re-establishment of activity upon the addition of guinea pig complement, increase in hemolytic activity of the serum when it was kept at icebox temperature overnight, gradual diminution in hemolytic activity with prolonged standing at icebox temperature, diminution of hemolytic activity when the serum was incubated with its clot, suppression of hemolytic activity upon incubation at 37.5°C with normal human serum before the red cell suspension was added, incomplete inhibition of hemolysis when the serum was mixed with normal human serum and allowed to

stand at room or icebox temperature before addition of the testing cells, and finally, an individual variability in the hemolytic susceptibility of cells from different subjects of the same blood group.

The microscopic picture of the spleen differed in all 3 cases, congestion and multiple thromboses being present in Case 1, reticuloendothelial proliferation and erythrophagocytosis being the outstanding features of Case 2, and simple congestion of the pulp characterizing Case 3. Extracts of the spleen were made in Cases 2 and 3, and various fractions showed a marked hemolytic quality.

DISCUSSION

Since 1925, the date of Lederer's first report on "acute (febrile) hemolytic anemia,"² over 50 cases of this syndrome have been reported. In 1909 Chauffard and Vincent,¹ in a thorough study almost completely neglected in the literature, described under the title "Hémogloburie hémolytique avec ictère polycholique aigu," a case of acute hemolytic anemia corresponding clinically and hematologically in every respect to what is now frequently called Lederer's anemia. What is more, Chauffard and Vincent demonstrated in their case the presence of a very active hemolysin in the serum, which was "precocious" in type, intense in action, not secondary to blood destruction but apparently the cause of it, and of endogenous origin. It appears that in none of the cases of acute hemolytic anemia reported since the work of Chauffard and Vincent has an hemolysin been investigated, although some speculations have been made regarding its presence, and regarding the possible antilytic value of blood transfusion. In a few cases, an autoagglutinin has been found.

Our own findings are quite similar to those of Chauffard and Vincent, although because of present-day knowledge of the blood groups we have been able to extend them. The unusual activity of the hemolysins, which appear to be of endogenous origin, and which were found to possess a strong lytic action upon cells of their own type as well as upon those of Group O, serves to set them apart from the known isohemolysins. The latter are occasionally discovered in the course of isoagglutination compatibility tests done prior to transfusion. We have observed 2 such cases. As Wiener³ points out, isohemolysins of this type correspond in specificity to the isoagglutinins normally present in the serum. The commonest isohemolysin is of the alpha type, and is usually present in Group O serum, which contains alpha and beta agglutinins (and hemolysins). So far as we are aware, no hemolysin has yet been reported which is active against Group O cells, which indeed are theoretically incapable of being hemolyzed by isohemolysins.

The antilytic action of normal human serum as demonstrated in our experiments may have some bearing upon the therapeutic value of blood transfusions, which have usually been curative in acute hemolytic anemia albeit in several cases splenectomy has been required. The gradual diminution in activity of the hemolysins, with continued recovery of the patients, makes possible a causal relation between the hemolysin and the development of the hemolytic syndrome. The presence of large numbers of spherocytes in Case 3, with their subsequent diminution in association with diminution in titer of the hemolysin, indicates that the spherocytes and the hemolytic factor were closely related. In other words, it is possible that the hemolysin was the direct cause of the development of spherocytes. Certain experiments which will form the basis of another paper tend to confirm this speculation.

Acute hemolytic anemia may be related to paroxysmal (cold) hemoglobinuria, to paroxysmal nocturnal hemoglobinuria (Marchiafava⁶), to acquired hemolytic icterus,⁷ to hemolytic splenomegaly (Banti⁸) and even to congenital hemolytic jaundice. Studies now in progress in the latter disease have demonstrated hemolysins in 2 cases.

Although most cases of acute hemolytic anemia appear to respond effectively to transfusions, occasional cases, it must be remembered, are so severe that the more radical measure of splenectomy must be employed. This may be a life saving measure.

SUMMARY

In 3 cases of acute hemolytic anemia failing to respond to transfusion but responding dramatically to splenectomy, hemolysins of unusual activity were demonstrated. Since the hemolysins were active against red cells of Group O and their own type, they fail to correspond to any hitherto described hemolysin. Furthermore a hemolytic factor was demonstrated in splenic extracts of 2 of the 3 cases.

From this preliminary paper no definite conclusions can be drawn, but the evidence already at hand suggests that the hemolysin was causally related to the development of the disease, that it was of endogenous origin, and that it was the causative factor for the presence of spherocytic microcytes in the third case. These hypotheses are now under investigation.

CASE 24021

PRESENTATION OF CASE

First Admission A fifty-six-year-old Italian housewife entered the hospital because of left flank pain of one day's duration.

On the day before entry she rather suddenly developed steady aching pain in the left lumbar region which spread forward to the left lower side of the abdomen but not down to the genitalia. She felt feverish, but had no chills. She had no bloody urine, frequency, dysuria or other urinary symptoms.

For the previous ten years she had moderate dyspnea on exertion and moderate orthopnea, so that she used three pillows while sleeping. She had no edema, chest pain, cough or hemoptysis, but did have occasional night sweats. She took ten drops of a brown alcoholic medicine three times a day for this "heart trouble." Her past history was otherwise negative. Her family history was noncontributory.

Physical examination revealed a feverish, rather obese woman apparently suffering some pain. Her heart was enlarged to the left, 1 cm. beyond the left midclavicular line. The rhythm was grossly irregular, and there was a diastolic apical murmur with a loud first sound. The apex rate was 100 and the radial rate 92. The blood pressure was 120 systolic, 80 diastolic. The abdomen showed moderate left lower quadrant and left costovertebral tenderness.

The temperature was 100°F., the pulse 92. The respirations were 20.

The urine had a specific gravity of 1.014, contained 4 white cells per high power field, but was otherwise negative. The blood showed a red-cell count of 4,500,000 with 90 per cent hemoglobin and a white-cell count of 14,800. The urine culture was negative.

X-ray of the abdomen showed the left kidney markedly enlarged and the right kidney fairly small. There were no unusual areas of calcification visible in the region of the kidneys. An intravenous pyelogram showed that the dye was excreted promptly by the right kidney and not at all by the left. The right kidney pelvis, calices and ureter appeared normal. A retrograde pyelo-

gram showed no evidence of disease in the left kidney pelvis and calices.

For the first week after entry the temperature remained elevated, fluctuating between 100 and 102°F., but on the eighth day the chart became flat. On the fifth day a urine culture contained *Bacillus coli*. On the tenth day another intravenous pyelogram showed the same findings as before. A chest plate showed the transverse diameter of the heart definitely increased. There was also increase in size across the base, but the greatest prominence was downward to the left in the region of the ventricle. She was discharged on the fifteenth day.

Second Admission (five days later) She felt well for four days after discharge, except for slight burning on urination. On the fifth day, while urinating, she suddenly had a very severe pain in her right costovertebral angle and re-entered the hospital two hours later.

Physical examination revealed marked right costovertebral tenderness. The heart findings were essentially the same as on the previous entry, and her blood pressure was 120 systolic, 90 diastolic.

The temperature was 100°F., the pulse 96. The respirations were 20.

The blood gave a red-cell count of 4,690,000 with 70 per cent hemoglobin, and a white-cell count of 28,900, 98 per cent polymorphonuclears. An x-ray of the abdomen revealed no appreciable change from the previous examination. The costovertebral pain persisted and she remained completely anuric until the third hospital day, when she passed about 200 cc of urine which showed a specific gravity of 1.012 and a trace of albumin. It contained many white cells, but no red cells or casts. By that time she had become somewhat drowsy and was vomiting occasionally. Her temperature had risen to 102°F., and her white-cell count to 42,000. On the following day the nonprotein nitrogen of the blood was 87 mg per cent. Her temperature fell to normal, where it remained until death, and her white-cell count fluctuated between 14,000 and 28,000. On the fifth day she passed no urine, but on the following day catheterization produced 1300 cc., which showed a specific gravity of 1.010 and a slight trace of albumin. It contained many white cells and from 5 to 10 red cells per high-power field, but no casts. The stool on that day gave a 3+ guaiac test. Her condition had improved somewhat, and she appeared to be mentally clearer. However, on the seventh day her nonprotein nitrogen was 105 mg per cent. She passed about 500 cc of urine on that day and about 600 cc on the following day. On each day the urine had a specific gravity of about 1.012 and contained albumin, there were many white cells, but no red

cells or casts For the last three days she was in coma, and she died on the tenth hospital day

NOTES ON THE HISTORY

DR RICHARD C CABOT We have then, from the history alone, a person with a cardiac history of ten years who, though she has not been very well, seems to have been well enough to get around up to the very day before she came here, when she suddenly had pain in the left flank That is all we know The question is whether we can connect these two things

The urine was negative, and of especial interest is the fact that it contained no blood The x-ray examination showed a fairly small right kidney I take it they did not mean that it was abnormally small "There were no unusual areas of calcification visible in the region of the kidneys" In other words, there is no reason to think of stones

One of the questions we have to consider is why she was discharged, in view of the fact that she died so promptly soon after My guess is that they did not have much to offer in the way of treatment, and that the patient was restless and wanted to go home

At the second admission she had pain in the *right* costovertebral angle Nothing is said about pain in the left side at this time The white-cell count was 28,000 You remember that it was 14,000 at the last admission

The most important thing we have to face is the fact that she was in the hospital three days and passed no urine

DIFFERENTIAL DIAGNOSIS

This is a ten-year cardiac story with no cardiac symptoms There was no edema, and nothing in the lungs Her heart was doing fairly well in spite of absolute arrhythmia First she had left-sided and then right sided severe pain, associated with anuria, pyuria and a rising leukocyte count The only sure thing in any other part of the body is the guaiac test which showed something in the intestine, otherwise we have nothing to call attention to any other organ except the heart and the kidney

Let us consider the heart Here is a woman of fifty-six, an Italian, that means she is older than most people of our race at that age She has a heart that may perfectly well be that of mitral stenosis and could conceivably be due to other types of disease, but they are not so probable, I should say Her heart is enlarged, especially the base and the left ventricle, and she has what is called a diastolic murmur, not further characterized, at the apex, a sharp first sound and absolute arrhythmia—those things fitting together to make

us think of mitral stenosis It is queer, at fifty six, that she had had no symptoms until within ten years, but of course not at all unprecedented

If it was not mitral disease, what could it be? She has low blood pressure There is nothing to suggest the hypertensive types of heart trouble The heart was not so much enlarged as one would suppose it would be if she had had hypertension

Now that certainly is not the whole of it She also has had night sweats from time to time If she were French, I should think less of that—French people have night sweats a good deal of the time without any good reason that I can think of The night sweats suddenly link up with the fever she had here on two occasions The fever, however, was not lasting In both cases the temperature flattened out Nothing makes us think of tuberculosis of the kidney, except the fact that the organ is enlarged She never passed pus She has never had the bladder symptoms that usually go with a tuberculous kidney We have nothing to make us think of malignant disease or cystic kidney, which is ordinarily bilateral Embolism—first left and then right—seems to be the only thing one can say, and the only thing that displeases me is that it is so plain Long experience has taught me that if a diagnosis is perfectly easy, it is usually wrong I doubt if I can do better than that, however It seems to me that she had embolism first of the left and later of the right kidney, and died from anuria subsequent to the shutting off of kidney function There is no evidence of nephritis I see no reason why we should think of that from anything given here

Were the emboli septic or were they bland? They could be bland from a ball thrombus in the left auricular appendage with mitral stenosis, and we certainly can have fever and leukocytes with bland emboli On the other hand I have never seen a blood-leukocyte count of 41,000 with bland emboli, and it seems to me that the suddenly increasing white count suggests that the emboli were septic Septicemia was not the main cause of the death, however, it seems to me, but rather the cutting off of the blood supply and suppression of kidney function secondary to it But at least septicemia, if there was one, helped

I should suppose, then, that there had been a bacterial endocarditis on the mitral valve, not elsewhere in the heart I suppose there was an old mitral stenosis back of that The heart was not greatly enlarged, only moderately, as we should expect with mitral disease I see no reason to suppose anything wrong in the lungs or other organs except the kidneys But there is one problem that bothers me If she is throwing septic emboli into the kidneys, why not somewhere else? I cannot answer that It is against my diagnosis However,

it does not seem enough to suggest any alternative diagnosis. There may have been an embolus in the intestinal tract, though we have nothing but a guaiac test to back that up. In these cases at post-mortem we often find emboli in various organs although there was no suggestion of them during life. If there were emboli in the kidneys, I believe there were emboli elsewhere. Whether the autopsy was complete enough—Dr Mallory has told me that it was not complete—to show that, I do not know. I do not believe she would throw them only into the kidneys. The best diagnosis I can make is bacterial endocarditis on top of old mitral stenosis, with embolism, certainly septic embolism, of both kidneys.

DR GEORGE W. HOLMES: This x-ray film shows a distinct difference in the size of the kidneys. The left is nearly twice the size of the right. It is not particularly abnormal in shape. There is a suggestion at the border of a slight amount of lobulation, but it is not the kidney of cystic disease or tumor. With the intravenous dye there is evidence of non-function. We have then a large non-functioning kidney on the left with a normal kidney on the right. When the retrograde pyelogram is taken we find no dilatation of the kidney pelvis, no dilatation of the calices and no evidence of obstruction in the ureter. We now have a non-functioning kidney not due to obstruction in the ureter or pelvis, with no thinning of the cortex of the kidney such as one would expect with hydronephrosis. When we study the outlines of the calices and the pelves I should say they were normal—not enough variation to make a diagnosis of tuberculosis or even pyelitis, although I know that pyelitis may exist without x-ray evidence. We shall have to explain this absence of function on something very similar to what Dr Cabot has suggested.

DR CABOT: How about the right kidney? At the second entry she had pain on the right.

DR HOLMES: We have no examination at the time of the second entry, so far as I can tell, it was normal at the time of the first.

DR FULLER ALBRIGHT: I saw this patient only on the second admission. The one thing that disturbed us was why she had emboli going to both kidneys and nowhere else. We developed a fantastic theory about that. We thought that she had emboli to the left kidney first, which caused thrombosis of the left renal artery, and which subsequently backed up into the aorta and extended over into the opening of the other renal artery. We felt that she did not have bacterial endocarditis. We thought the emboli were aseptic. As a matter of fact she had a blood culture that was negative, I believe.

CLINICAL DIAGNOSES

Rheumatic heart disease with mitral stenosis and auricular fibrillation
Bilateral infarction of the kidneys
Uremia

DR CABOT'S DIAGNOSES

Old mitral stenosis probably with bacterial endocarditis
Septic emboli in both kidneys

ANATOMIC DIAGNOSES

Bland emboli to both renal arteries
Bilateral renal infarction

PATHOLOGICAL DISCUSSION

DR TRACY B. MALLORY: I think one of the difficult things in these clinical discussions is to bring oneself to make a diagnosis that seems obvious, and I might say that on years of experience Dr Cabot is one of the few who has consistently had the courage to do that. The diagnosis was primarily what he suggested—bilateral renal embolism. We found multiple infarcts of varying ages in both kidneys, the ones on the left being distinctly older than those on the right, but within each kidney there were infarcts of somewhat varying age.

Unfortunately the autopsy was limited to the abdomen so we could not see what the heart valves showed. Whether there was a bacterial endocarditis or simply an old rheumatic stenosis, we could not check with certainty. We could see from examination of the kidneys that these emboli were certainly not frankly septic. In other words there could not have been a bacterial endocarditis with a pyogenic organism such as a streptococcus or pneumococcus. I think we can guess a little further and say that it was probably not a bacterial endocarditis. In the kidney tissue between the infarcts, and there were a significant number of uninfarcted areas, we did not find the lesion which is so characteristic of *Streptococcus viridans* endocarditis, so-called embolic nephritis with individual glomerular lesions. That does not absolutely rule out bacterial endocarditis, it simply is of inferential value.

We were surprised at the autopsy—as Dr Cabot and Dr Albright were from the clinical course—that there was no evidence of embolism elsewhere. We did not have permission to examine the head but the spleen, the other abdominal organs and the gastrointestinal tract were all entirely negative and the only evidence of embolism that was found was in the kidneys.

DR BRAILEY Is it not peculiar that she had these two dramatic episodes of pain and that the kidneys should shut down on the basis of multiple emboli?

DR MALLORY We have seen pain and complete suppression of urine with renal infarcts before. I think they usually have been very massive ones. We have, I am sure, seen a white-cell count go as high as 40,000 with bland infarction.

DR. CABOT There was no embolus in any of the big vessels?

DR MALLORY One large embolus was found lying nearly free in the right renal artery, but it had not completely occluded it. On both sides there were multiple occlusions of small arteries.

A PHYSICIAN What was the explanation of one kidney being so much larger than the other?

DR MALLORY That was at the first examination, when only the one kidney was involved.

DR CABOT At autopsy they were nearly the same size?

DR MALLORY Yes.

DR CABOT And both large?

DR MALLORY Yes.

CASE 24022

PRESENTATION OF CASE

A twenty-four-year-old white Greek housewife entered the hospital with a complaint of cough and fever of nine days' duration.

Nine days before entry she awoke in the morning with a headache and dizzy feeling. During the day she felt feverish and passed frequent, small amounts of cloudy urine. That evening she had a severe chill and perspired profusely. Her physician examined her urine and told her she had an infection in her kidney. He gave her some pills, and her condition improved somewhat in the next few days. The urinary symptoms lasted three or four days. The temperature continued to be elevated and she had mild intermittent pain just under the left ribs. Six days before entry she began to have moderately severe, sharp, pulsating pain in the lower right anterior chest which was not influenced by breathing. The following morning she developed a dry cough and sore throat. Her fever increased and she soon began to raise dark black tenacious sputum, which was not blood streaked. The day before admission she developed a "fever blister" on her upper lip, and she also became somewhat dyspneic. She had had her last menstrual period seven weeks before entry and in the weeks before entry had some morning nausea and vomiting.

The family history was negative except that one brother had tuberculosis and was in a sanatorium. She had very infrequent colds and no previous car-

diorespiratory symptoms. Nine months before entry just after the birth of her second child she had urinary symptoms lasting a week similar to those in her present illness. She had had two normal pregnancies, the first child dying of "meningitis" at the age of eight months. The past history was otherwise negative.

Physical examination revealed a well-developed, well-nourished, not acutely ill, somewhat dyspneic, perspiring female. Examination of the chest was negative except for increased voice sounds in a small area posteriorly between the angle of the scapula and the lower dorsal ribs on the right. The blood pressure was 120 systolic, 90 diastolic. Pelvic examination revealed bluing of the introitus and a soft patulous cervix.

The temperature was 103°F, the pulse 120. The respirations were 24.

The urine had a specific gravity of 1.010 and contained 5 to 10 white cells per high-power field in the sediment. The blood showed a red-cell count of 4,270,000 with 80 per cent hemoglobin. The white-cell count was 20,200, 84 per cent polymorphonuclears. No tubercle bacilli were found in the sputum on repeated examination, and the stools were negative. The blood-serum chlorides were equivalent to 87 cc N/10 sodium chloride. Blood cultures were twice negative, and a sputum culture contained many hemolytic streptococci. A blood Hinton test was negative.

An x-ray of the chest revealed an area of cloudy consolidation in the second right interspace, particularly around the hilus. The lung fields were otherwise clear. The costophrenic angles were clear, and the heart was not remarkable.

On the day after entry the temperature rose to 105°F and the respirations to about 40. She became slightly cyanotic and was put in an oxygen tent. On that day she had an attack lasting about ten minutes in which she became disoriented and moved her right arm convulsively. The temperature at the time was 106°F. For the next week the temperature remained high, never falling below 101 and often rising to 105°F. On the fourth day she complained of headache, stiffness of the neck and some inability to use the right leg, but no reflex changes. Examination of the chest was essentially the same as before. On the following day she suddenly began to pass red blood and clots from her vagina. She bled freely, but her general condition remained unchanged. After a few hours she expelled an intact placenta and was immediately given pituitrin and ergot. The blood pressure remained unchanged and the bleeding lessened considerably. On that day she had another cerebral attack similar to the previous episode and lasting a few minutes. Her head turned to the right, her eyes rolled about, and her right arm

moved in tonic contractions. However, she did not lose consciousness. Neurological examination revealed no cranial nerve involvement. The neck was moderately stiff, but the Kernig was negative. There was marked weakness of the right arm with decreased activity of its reflexes. No sensory changes could be made out. A lumbar puncture was performed, but only a few cubic centimeters of bloody fluid could be obtained. The respiratory and pulse oscillations were fair, and the initial pressure was 150. The spinal fluid contained 25,000 red cells and 2100 white cells per cubic millimeter, with 68 per cent polymorphonuclears and 32 per cent lymphocytes, 198 mg per cent of protein and 38 mg per cent of sugar. No tubercle bacilli or other bacteria were seen on direct smear.

Three days later, on the ninth hospital day, she became somewhat drowsy, her neck became stiffer, and the Kernig was positive. Otherwise, the neurological examination was essentially the same as before. A lumbar puncture yielded only 1 or 2 cc. of bloody fluid. The vaginal discharge, which had been scant, increased in amount and became foul smelling. The blood at that time showed a red-cell count of 3,650,000 with 60 per cent hemoglobin. The white-cell count was 19,500, 90 per cent polymorphonuclears. An x-ray of the chest the following day showed the area of increased density in the region of the right hilus to be slightly smaller than before, and its upper portion seemed somewhat less dense, suggesting cavitation. Neurological examination revealed that she had developed a definite right facial lesion of the central type. She was started on prontosil in a dosage of 80 gr daily, and the temperature dropped quite sharply to 99°F., without change in pulse or respirations. However, it rose slightly the next day, and the following day, which was the eleventh hospital day, it reached 104°F. It remained at about that level until death. The serum chlorides of the blood were equivalent to 98 cc of N/10 sodium chloride. The carbon-dioxide combining power was 44.5 vol per cent. On the thirteenth hospital day she developed a right external strabismus, and her right leg became flaccid. She was given a clysis of 1000 cc of 2.5 per cent dextrose in saline with 100 cc of prontosil, and on the following day a clysis of 1000 cc of dextrose and saline with 200 cc of prontosil. She died that day.

DIFFERENTIAL DIAGNOSIS

DR ALFRED O LUDWIG. The onset of this patient's illness certainly suggests that she had some acute infectious process, since it was marked by headache, fever and chills, as well as by sweating. The urinary symptoms and her physician's statement of the examination of the urine would lead one to believe that he was correct in making the

original diagnosis of a urinary infection. This might well have been pyelitis and cystitis. Three days after the onset we first hear of chest pain situated in the right anterior chest, and this, as it is recorded here, does not suggest a pleuritic type of pain since it was not associated with breathing. One wonders whether possibly the pain was associated with something under the diaphragm, with a rather unusual reference of pain to the lower anterior chest. Soon afterward the patient began to develop respiratory symptoms in the nature of cough and sore throat. The development of herpes would be consistent with almost any infection associated with high fever, but is perhaps more commonly seen with the high temperatures during the course of pneumonia and very often with meningococcal meningitis. The onset of dyspnea also suggests that there has been some extension of the process to the patient's chest. The menstrual history associated with what we learn later in the history makes a diagnosis of pregnancy quite evident.

In the patient's past and family history it is significant that she had one brother who had tuberculosis, but we are not told whether she was in contact with him. It is interesting that the patient also had urinary symptoms after the birth of her second child, nine months before this illness. It would seem quite likely that this may also have been a pyelitis, and it is known that patients who have a pyelitis during pregnancy not infrequently have a recurrence with subsequent pregnancies. It might also lead one to think that in addition to the pyelitis there might actually have been some pyelonephritis, but I do not believe that this had led to any serious impairment of kidney function. We should like to know more about the exact cause of death of her first child—what the nature of the meningitis was. If this had been tuberculous it would be of considerable importance in the differential diagnosis of the patient's illness.

Physical examination tells us that we have a patient who was probably suffering from some acute infection involving her lung, and the finding of an area of increased voice sounds on the right side leads one to believe that there was a small area of consolidation there. Pelvic examination confirms the diagnosis of pregnancy.

A finding of 5 to 10 white cells in the urinary sediment in a female patient is not of significance unless the specimen was obtained by catheter. It is perhaps of note that the specific gravity was only 1.010, unless the patient had been forcing fluids one would expect that with the high fever and profuse sweating the urine would be quite concentrated. The red-cell count indicating a slight anemia and the leukocytosis with the predomi-

DR BRAILEA Is it not peculiar that she had these two dramatic episodes of pain and that the kidneys should shut down on the basis of multiple emboli?

DR MALLORY We have seen pain and complete suppression of urine with renal infarcts before. I think they usually have been very massive ones. We have, I am sure, seen a white-cell count go as high as 40,000 with bland infarction.

DR CABOT There was no embolus in any of the big vessels?

DR MALLORY One large embolus was found lying nearly free in the right renal artery, but it had not completely occluded it. On both sides there were multiple occlusions of small arteries.

A PHYSICIAN What was the explanation of one kidney being so much larger than the other?

DR MALLORY That was at the first examination, when only the one kidney was involved.

DR CABOT At autopsy they were nearly the same size?

DR MALLORY Yes.

DR CABOT And both large?

DR MALLORY Yes.

CASE 24022

PRESENTATION OF CASE

A twenty-four-year-old white Greek housewife entered the hospital with a complaint of cough and fever of nine days' duration.

Nine days before entry she awoke in the morning with a headache and dizzy feeling. During the day she felt feverish and passed frequent, small amounts of cloudy urine. That evening she had a severe chill and perspired profusely. Her physician examined her urine and told her she had an infection in her kidney. He gave her some pills, and her condition improved somewhat in the next few days. The urinary symptoms lasted three or four days. The temperature continued to be elevated and she had mild intermittent pain just under the left ribs. Six days before entry she began to have moderately severe, sharp, pulsating pain in the lower right anterior chest which was not influenced by breathing. The following morning she developed a dry cough and sore throat. Her fever increased and she soon began to raise dark black tenacious sputum, which was not blood streaked. The day before admission she developed a "fever blister" on her upper lip, and she also became somewhat dyspneic. She had had her last menstrual period seven weeks before entry and in the weeks before entry had some morning nausea and vomiting.

The family history was negative except that one brother had tuberculosis and was in a sanatorium. She had very infrequent colds and no previous car-

diorespiratory symptoms. Nine months before entry just after the birth of her second child she had urinary symptoms lasting a week similar to those in her present illness. She had had two normal pregnancies, the first child dying of "meningitis" at the age of eight months. The past history was otherwise negative.

Physical examination revealed a well-developed, well-nourished, not acutely ill, somewhat dyspneic, perspiring female. Examination of the chest was negative except for increased voice sounds in a small area posteriorly between the angle of the scapula and the lower dorsal ribs on the right. The blood pressure was 120 systolic, 90 diastolic. Pelvic examination revealed bluing of the introitus and a soft patulous cervix.

The temperature was 103°F., the pulse 120. The respirations were 24.

The urine had a specific gravity of 1.010 and contained 5 to 10 white cells per high-power field in the sediment. The blood showed a red-cell count of 4,270,000 with 80 per cent hemoglobin. The white-cell count was 20,200, 84 per cent polymorphonuclears. No tubercle bacilli were found in the sputum on repeated examination, and the stools were negative. The blood-serum chlorides were equivalent to 87 cc N/10 sodium chloride. Blood cultures were twice negative, and a sputum culture contained many hemolytic streptococci. A blood Hinton test was negative.

An x-ray of the chest revealed an area of cloudy consolidation in the second right interspace, particularly around the hilus. The lung fields were otherwise clear. The costophrenic angles were clear, and the heart was not remarkable.

On the day after entry the temperature rose to 105°F and the respirations to about 40. She became slightly cyanotic and was put in an oxygen tent. On that day she had an attack lasting about ten minutes in which she became disoriented and moved her right arm convulsively. The temperature at the time was 106°F. For the next week the temperature remained high, never falling below 101 and often rising to 105°F. On the fourth day she complained of headache, stiffness of the neck and some inability to use the right leg, but no reflex changes. Examination of the chest was essentially the same as before. On the following day she suddenly began to pass red blood and clots from her vagina. She bled freely, but her general condition remained unchanged. After a few hours she expelled an intact placenta and was immediately given pituitrin and ergot. The blood pressure remained unchanged and the bleeding lessened considerably. On that day she had another cerebral attack similar to the previous episode and lasting a few minutes. Her head turned to the right, her eyes rolled about, and her right arm

of the infection is that on one occasion hemolytic streptococci were cultured from the sputum. There is nothing in the story inconsistent with a severe streptococcal infection and subsequent septicemia.

Is it possible to reconstruct the events in the course of this patient's illness? If we follow what we are given, we will have to assume that her original urinary symptoms represent the onset of the illness which eventually caused her death or that the urinary infection was entirely unassociated. I believe it is perfectly possible that the infection may have begun in her kidneys. I believe she developed an extensive bronchopneumonic process probably due to the streptococcus, and it is very characteristic of these lesions to break down rapidly and cavitate. This type of pulmonary lesion is hemorrhagic in nature, similar to those that are described as having occurred during the influenza epidemic of 1918.

We still have to explain the cause and the nature of her neurologic symptoms. As mentioned above, I believe there can be no doubt this patient actually had infection in her meninges. It is possible that the blood which was found in the spinal fluid was related to the original lesion, perhaps due to thrombosis of a vessel with subsequent hemorrhage, but one cannot be sure of this. The blood was more likely due to trauma incident to performing the lumbar puncture. I believe that the patient had a definite meningitis caused by the same organism which was responsible for her pneumonia, presumably a streptococcus, and this in itself would have been enough to explain all the neurologic findings. The other possibility is that the patient, having developed abscesses in her lung, had a metastatic lesion in her brain secondary to this. This lesion would have to be located in the region of the left motor cortex, as all of her neurologic signs were on the right side. The sudden onset of these symptoms is perhaps somewhat in favor of an embolic lesion which later went on to true abscess formation, in other words, a septic embolus. If the patient had a septicemia, metastatic lesions of course might have developed anywhere. There is one other possibility which should be thought of as having produced metastatic lesions. If this patient did have a septicemia, she may also have had an acute endocarditis, perhaps even with acute vegetations containing organisms. If this was so, again, metastatic lesions could have developed anywhere. But we have no evidence that the patient did have septic endocarditis, and she certainly did not have clinical evidence of emboli elsewhere.

Although we have very little to go on, it is interesting to speculate as to whether this patient

had a renal lesion of any severity. We have only one urine examination, and I have already spoken of the discrepancy in the specific gravity. If this was confirmed by subsequent examination,—that is, if the specific gravity remained consistently low, showing inability of the kidney to concentrate,—we might suspect this patient did have some degree of pyelonephritis secondary to this and the previous attack of urinary infection, both associated with pregnancy. In patients who have repeated urinary infections, we not infrequently find congenital anomalies of the urinary tract. It is possible, of course, that these may be present, but we have no evidence of them. I do not believe tuberculosis has to be seriously considered in differential diagnosis even though there are some hints in this direction in the past and family histories. The x-ray findings are not at all those of tuberculosis, and as stated above, I believe tubercle bacilli would certainly have been found if the pulmonary infection were due to this cause. We also have nothing to make us believe that this patient was suffering from miliary tuberculosis. The one other possibility is that the lesion at the right hilus might have represented tumor. If this was so, it is quite within reason that, if the lesion was located in a bronchus, secondary obstruction and subsequent abscess formation might have taken place. I do not believe that we have enough evidence to consider tumor as more than a very remote possibility. Finally, the patient may have had some uterine infection following her abortion.

I believe then that this patient was suffering from a severe streptococcal infection with a streptococcal pneumonia and secondary abscess formation, that she probably had a blood-stream infection with a metastatic lesion in her brain in the region of the left motor cortex, with secondary meningitis, and there may have been some endometritis. I believe that some degree of pyelonephritis may have been found at the postmortem examination.

CLINICAL DIAGNOSES

Lung abscess, postpneumonic
Brain abscess
Meningitis?
Miscarriage

DR LUDWIG'S DIAGNOSES

Abortion
Streptococcal pneumonia with abscess formation
Streptococcal septicemia
Cerebral abscess
Streptococcal meningitis
Endometritis?
Pyelonephritis?

nance of polymorphonuclears in the smear are consistent with infection. I believe that the absence of tubercle bacilli in the sputum on repeated examinations almost certainly rules out tuberculosis as a cause of her pulmonary symptoms. The blood chloride value of 87 cc N/10 sodium chloride tells us that the patient's chlorides were depleted, probably due to chloride loss from excessive sweating. I do not know whether one can lay too much significance on the finding of hemolytic streptococci in the culture of the sputum, as these are very frequently found, even in the throats of normal individuals.

According to the radiologist, the x-ray findings of the area of consolidation around the right hilus and also clouding of the whole right lower and middle lobe are indicative of infection in the lung. The findings do not suggest infarct, as this lesion is usually found in the periphery. Tumor is a possibility, but the radial markings extending out into the lung field from the hilus shadow are not those typically seen in cases of malignancy.

Subsequently, the patient became progressively worse, with an increase of temperature and respirations, cyanosis, and the appearance of a new symptom, namely an attack of disorientation and convulsive movements limited to one side of the body and at first only to one arm. This episode was apparently associated with a marked increase in temperature to 106°F, and from that time on the temperature took on an irregular or septic type of swing. We then note evidence of meningeal irritation with headache and stiffness of the neck. At this point the patient's pregnancy was spontaneously terminated, as evidenced by the passage of blood and clots by the vagina. If the dates are correct, one would not expect a placenta to have developed, and I should say that the statement that an intact placenta was passed should have read "an intact ovum was passed." The occurrence of abortion under these circumstances is not at all unusual, in fact in pneumonia associated with pregnancy the usual course is abortion during the course of the infection. The patient then had another cerebral attack, with her head turning to the right and with convulsive movements of the right arm. The localizing symptoms we have had in connection with her neurologic lesion have all pointed to the left motor cortex. At this time we again note stiffness of the neck and also weakness of the right arm. Lumbar puncture, while its results are somewhat unsatisfactory, is of considerable help in establishing the nature of the lesion. The initial pressure was within normal limits, and respiratory and pulse oscillations were normal. So far as the findings in the spinal fluid are concerned, one cannot be certain whether the red cells present were

secondary to the tap or whether they actually came as the result of the cerebral lesion. If we calculate the number of white cells that would be expected with 25,000 red cells, according to the method described by Solomon, allowing 1 white cell for every 700 red cells, we obtain 300 white cells, and subtracting this from 2100, we still have some 1800 white cells to account for. Again, the protein of 198 mg as compared with a normal of from 15 to 45 mg is markedly increased. We can account for the amount of protein which would have been added to the spinal fluid by the presence of blood serum by allowing 1 mg increase in the protein for every 750 red cells. This, however, gives an increase of only 33 mg, so that we still have 150 mg to account for on another basis. The normal value of the sugar in the spinal fluid is around 60 mg, and here it is decreased by almost half. The differential count of the white cells shows a predominance of polymorphonuclears, and this along with the increased protein and the low sugar are, to me, very definite evidence of bacterial infection within the meninges. We then note that her vaginal discharge increased in amount and became foul smelling. This may indicate imperfect involution of the uterus, or even the onset of uterine infection. A red-cell count at this time showed that the patient had developed a somewhat more marked degree of anemia than was present at entrance. This might have been secondary either to her rather severe infection, to bleeding following the abortion, or to both.

An x-ray at this time showed a definite area of cavitation in the shadow at the right hilus region noted before, and at this time the neurological examination showed more definite signs localizing a lesion in the region of the left motor cortex. We then find a note that the patient was started on prontosil, I suppose because it was suspected she was suffering from a severe streptococcal infection. Apparently her chlorides had been depleted, as a second determination showed a normal value of 98 cc of N/10 sodium chloride. The carbon-dioxide combining power, however, was definitely decreased, indicating some acidosis. This may have been secondary to her infection but it has also been described following the administration of prontosil. The neurological findings increased, with the development of an external strabismus on the right and a paralyzed right leg.

There is little doubt in my mind that this patient was suffering from some very severe infection. From the nature of her temperature chart I should strongly suspect, even though the blood cultures were negative at various times during her stay in the hospital, that she had a blood stream infection. The only clue we have as to the nature

LAWS FOR PURE FOOD, DRUGS, AND COSMETICS

THE inadequacy of the existing Federal Food and Drugs Act is strikingly demonstrated by the fact that seizures of the toxic Elixir Sulfanilamide (Massengill) could be made only on the charge that the word "elixir" implied an alcoholic solution, whereas this product was a diethylene-glycol solution. Astonishing as it may seem, had the product been properly labeled a "solution," not an "elixir," no charge of violation of the law could have been brought against the company that had sold a product which, when used as directed, had caused many deaths.

This example should be shocking enough to arouse the medical profession to action on the pure food and drugs act now before Congress.

The United States Department of Agriculture in its recent report on "Deaths due to Elixir Sulfanilamide, Massengill" makes certain recommendations for legislation to protect the public from drugs which are dangerous because of their inherent toxicity. The recommendations are

1 License control of new drugs to insure that they will not be generally distributed until experimental and clinical tests have shown them to be safe for use. The definition of what constitutes a new drug should include (a) substances which have not been used sufficiently as drugs to become generally recognized as safe, (b) combinations of well known drug substances where such combinations have not become generally recognized as safe, and (c) well known drug substances and drug combinations bearing label directions for higher dosage or more frequent dosage for longer duration of use than has become generally recognized as safe.

Exemption should be made for new drugs distributed to competent investigators for experimental work. A board of experts should be provided which will advise the Secretary of Agriculture on the safety of new drugs.

It is the department's view that no other form of control will effectively safeguard the public from the dangers of premature distribution of new drugs. To increase the penalties for violations and to require label disclosure of ingredients would be helpful, but by no means fully adequate.

In the interest of safety, society has required that physicians be licensed to practice the healing art. Pharmacists are licensed to compound and dispense drugs. Electricians, plumbers, and steam engineers pursue their respective trades under license. But there is no such control to prevent incompetent drug manufacturers from marketing any kind of lethal potion. It should be remembered that Doctor Massengill and his chemist Watkins are far better equipped from the standpoint of technical training than many other persons now engaged in the manufacture of drugs.

2 Prohibition of drugs which are dangerous to health when administered in accordance with the manufacturer's directions for use. This would provide a more appropriate basis of action than that on which proceedings were instituted against the elixir. A number of dangerous drugs are now on the market against which not even a trivial charge of violation can be made.

3 Requirement that drug labels bear appropriate directions for use and warnings against probable misuse. Much injury results from insufficient directions and from lack of warning against overdosage, or administration to children, or use in disease conditions where the drug is dangerous, or possibility of drug addiction.

4 Prohibition of secret remedies by requiring that labels disclose fully the composition of drugs. Many foreign countries now impose this requirement. Many

ANATOMIC DIAGNOSES

Bronchopneumonia, with abscess formation
Cerebral abscesses, multiple
Meningitis
Septic infarction of the spleen and liver
Postpartum uterus

PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY The autopsy on the whole sustained Dr Ludwig's clinical diagnoses and also showed in addition a very interesting and rare lesion which was not foreshadowed in any of the clinical signs or symptoms

We found an abscess of the lung which was located in the apical portion of the right lower lobe. The lung for some distance around the abscess was consolidated, and both the location of the lesion and its appearance favor the assumption of secondary abscess formation in a pneumonic area rather than the commoner type of abscess which followed inhalation of septic material. There was an extensive terminal bronchopneumonia scattered throughout all the remaining lobes.

The central nervous system showed not only a meningitis but abscess formation. The rather indefinite localizing signs of abscess, however, are probably to be explained by the fact that three separate abscesses were present, one of which involved the left motor area, whereas the other two were in the posterior left parietal region and in the wall of the posterior tip of the right lateral ventricle. This last abscess had broken into the ventricle and there is very little doubt that this accident initiated the meningitis. The meningeal exudate was not in the least hemorrhagic, so that the blood which was obtained on lumbar puncture must have been due to trauma.

The genital organs showed a slightly enlarged uterus with a shaggy scar of the placental attachment measuring 2 cm in diameter. There was no evidence of severe infection. The left ovary contained a corpus luteum of pregnancy.

We could find nothing in the kidneys to indicate a pyelonephritis, but the mucous membrane of the pelves and also that of the ureters and bladder were stained a deep red by the sulfanilamide which had been given.

From the pathological point of view the most interesting feature of the autopsy was the liver. Both on the external and the cut surfaces it showed a remarkable mottling of light brown and purple areas. The purple areas varied from the size of a single lobule up to several centimeters in diameter. Within these areas the divisions of the portal vein contained thrombi, some of which were attached to the intima, whereas others lay quite loose within the veins and had all the characteristics of emboli. Although portal thrombosis is by no means rare, clear evidence of gross embolism within the portal circulation is entirely new in my experience. Moreover, infarction of the liver, which is what the purple discoloration turned out to be due to, is also extremely uncommon because of the liver's double blood supply from both the portal vein and the hepatic artery. The usual source of portal thrombosis is infection in the gastrointestinal tract. That was not the case here, however, and it proved possible to find the source of the emboli. Two septic infarcts were present in the spleen, and a branch of the splenic vein immediately adjacent to one of these infarcts contained a thrombus. I think there can be little question that this thrombus at one time extended farther along the splenic vein and that fragments detached from it were responsible for the infarction in the liver.

From the bacteriological point of view the autopsy findings were rather equivocal. The autopsy was done twenty hours post mortem. The heart's blood, surprisingly enough, was sterile. Cultures from the lung abscess, the various brain abscesses and the spleen showed multiple organisms, including *Bacillus coli*, staphylococci, and non hemolytic and alpha-hemolytic streptococci. No beta-hemolytic streptococci were recovered.

OBITUARY

EDWARD AUSTIN ANDREWS

1871-1937

EDWARD AUSTIN ANDREWS was born in Wetmore, Kansas, April 7, 1871

In 1896 he was graduated from the Harvard Medical School, and spent the following five years on the staff of the Children's Hospital before coming to Newton where he practiced his profession for over thirty-five years

During this time he served for twenty-three years on the medical staff of the Newton Hospital, retiring one year ago because of age limit. He played a prominent part in drawing up rules for the safe handling of milk in the City of Newton. These rules were copied by other communities and later led to the general pasteurization of milk.

In addition to his medical duties, he gave generously of his time for the benefit of the city. For fourteen years, he was president of the Newton Centre Improvement Association and was influential in obtaining the Newton Centre library building, various playgrounds and the bathing facilities at Crystal Lake.

Doctor Andrews served the Newton Hospital well. The younger members of the profession will miss him because he was always ready and willing to give them advice, we older members shall miss him because of our many associations with him in one cause or another.

CASE HISTORY No 54 BLEEDING AT SEVENTH
MONTH—CENTRALLY IMPLANTED
PLACENTA PREVIA

Mrs F. K., a thirty-seven-year-old gravida VII, was admitted to the hospital on October 3, 1937, in the seventh month of gestation, complaining of painless vaginal bleeding of two days' duration.

A series of selected case histories by members of the section will be published weekly.
Comments and questions by subscribers are solicited and will be discussed by members of the section.

The family history was negative for malignancy, diabetes, pulmonary tuberculosis and chronic nephritis. The patient had never had a serious illness and had never been operated upon. Menstruation began at fourteen years of age with a twenty-eight-day cycle. Her last menstrual period began on March 7. One pregnancy resulted in a premature stillbirth, there were two early miscarriages and three normal-term pregnancies.

Within a week after the first missed period the patient began to spot daily. This slight bloody show continued off and on until admission to the hospital, there were two moderately severe hemorrhages which were treated by rest and sedatives at the patient's home and a third hemorrhage which began two days before admission.

On admission to the hospital the patient was bleeding very little. Examination showed moderate pallor of the conjunctivae, lips and finger tips. The pulse was weak, and the rate 110 per minute. The pupils reacted to light and accommodation, and all extraocular movements were normal. There was no nasal obstruction. The teeth were in good repair and oral hygiene was excellent. The thyroid was slightly enlarged. The heart was not enlarged, there were no murmurs. The lungs were clear and resonant, there were no rales. The fundus was two fingerbreadths above the umbilicus, and the fetal heart was heard in the midline. All reflexes were normal, and there were no varicosities of the extremities.

A blood count showed 2,700,000 erythrocytes and a hemoglobin of 62 per cent (Sahlb). The urine was acid, with a specific gravity of 1.012 and no albumin or sugar, the microscopic examination showed squamous epithelium and detritus.

Complete rest in bed and careful observation were instituted. A slight blood loss occurred on several occasions during the next five days. On October 8 under perfect asepsis, digital and specular examinations were performed. The cervix was normal in appearance, not taken up, not patulous, and contained no polyp or erosion from which the bleeding might have come. Bimanual examination revealed a feeling of fullness between the cervix and the presenting part. A presumptive diagnosis of central placenta previa was made, and the patient was returned to bed. The following day she was given 500 cc of citrated blood. About five minutes after the completion of the transfusion a reaction occurred characterized by dyspnea, substernal oppression and a rapid thready pulse. The administration of 1/6 gr of morphine and 0.5 cc. of adrenalin (1:1000) afforded considerable relief, and ten minutes later her condition improved and the above symptoms gradually subsided.

It seemed unwise to delay operation, although it was appreciated that the baby, because of prema-

drugs manufactured in the United States are exported to such countries under labels bearing such disclosure. The same drugs are sold to our citizens under labels that give no hint of their composition.

The physician, and the consumer who acts as physician to himself, both have a right to know what they administer.

The foregoing recommendations are limited to provisions which the department believes should be enacted to safeguard the public from the dangers of drugs of one type. That type includes the inherently toxic drugs, such as the elixir,¹ dinitrophenol and cinchophen. Many additional points should be considered if adequate protection is to be extended against even more widespread dangers to health and other abuses of public welfare arising from the inadequate control authorized by the present law over various other types of drugs.

The inclusion of these recommendations in the pure food and drugs act that is now being considered by Congress should be insisted upon by the medical profession. Moreover, to strengthen this law the profession should urge that the regulation and enforcement of this act be under the control of the Food and Drug Administration of the Department of Agriculture. Division of responsibility between the Food and Drug Administration and the Federal Trade Commission is disadvantageous, but is now being advocated by those interests that wish to weaken the act.

A letter from Dr. Henry Christian published in this issue of the *Journal* tells how physicians can meet their obligation in this matter. Unless they do so, the public may well feel that the profession's support of legislation which prohibits the sale of just such drugs as sulfanilamide, dinitrophenol and cinchophen except by prescription of a physician is based on self-interest rather than on concern for the public's well-being.

THE LICENSING OF HOSPITALS

THE report of the Special Commission to Study and Investigate Public Health Laws and Policies, authorized by the Massachusetts Legislature of 1935, and continued by the 1936 session, was made public December 2, 1936, and acted on by the Legislature in 1937.

The commission submitted the draft of a bill¹ which, if enacted, would provide for the licensing of all hospitals in Massachusetts by the Depart-

ment of Public Health, except mental disease hospitals and those operated by the United States Government and the Commonwealth. The proposed bill also provides that local boards of health "shall have first certified to the Department of Public Health that the hospital applying for such license is approved as to location and equipment." The bill would confer on the department authority to make rules and regulations governing the operation of hospitals and would permit local health and police departments to visit and inspect the licensed hospital. Under existing law, maternity hospitals and obstetrical wards in general hospitals are licensed by the Department of Public Welfare, the proposed bill should provide that this function be transferred to the Department of Public Health, for otherwise complications might arise. The House passed the bill submitted with a few amendments, but it was rejected by the Senate in the last day of the session.

The advisability of an act requiring the licensing of hospitals seems reasonable, for although certain organizations publish lists of approved hospitals, there is no authority compelling observance of good administrative methods for the general or private hospitals in Massachusetts. The public should have the assurance of at least average quality of hospital service. Other institutions where medical care is provided, such as nursing homes and accommodations for the aged, should also be included in this licensing scheme.

The bill of last year was sponsored by the Massachusetts Hospital Association and approved by many physicians, and it is expected that a similar bill will be drawn and submitted to the Legislature of 1938.

The arguments in favor of the enactment of a suitable law providing for the licensing of hospitals, which appear in the report² of the commission, are logical and should be read by all who are interested in safeguarding the interests of the several classes of inmates of the institutions to which reference has been made.

RECENT DEATH

SMITH—CHARLES MORTON SMITH, M.D., died at his home, 437 Marlboro Street, Boston, January 8. He was in his seventy second year.

Born in Dublin, New Hampshire, he was educated in the public schools there, attended Harvard College and was graduated from Harvard Medical School in 1893. He served an internship at the Boston City Hospital and returned to Harvard Medical School in 1895 to do post graduate work.

Dr. Smith, one of the country's foremost authorities on syphilis, was professor emeritus of syphilology at the Harvard Medical School. An expert on genital syphilis, he served at the Boston Dispensary under Dr. Abner Post, American pioneer in syphilis research and treatment. Dr. Smith had been chief of the syphilis clinic of the Massachusetts General Hospital for fifteen years.

Among his affiliations were memberships in the American Dermatological Association, the New England Dermatological Society, the American Board of Dermatology and Syphilology, the Harvard Club of Boston, and the Roxbury Clinical Record Club, of which he was president at the time of his death. He was a fellow of the Massachusetts Medical Society and of the American Medical Association.

He leaves his widow, the former Mary L. Moulton, a son, Morton Smith, of Wellesley Hills, a daughter, Mrs. William D. Van Alstyne, of Princeton, N. J., and a sister, Mrs. F. Cora Graves, of Westboro.

REPORT OF MEETING

HARVARD MEDICAL SOCIETY

A meeting of the Harvard Medical Society was held on November 23 at the Peter Bent Brigham Hospital, Dr. James P. O'Hare presiding.

The first case was presented by Dr. Clark. The patient was a 52-year-old Jewish, married male. For over 20 years he had shown some bacteria and occasionally had shown a small amount of albumin in his urine. Eleven years before entry he had first shown pus cells in his urine and at this time the diagnosis of bilateral hydronephrosis and hydroureter was made by pyelography and cystography. There was a marked cystitis and a marked bilateral infection of the upper urinary tract. Since that time he had been followed in the Outpatient Department. The infection had persisted but had not been marked until one year before entry, when there was a severe exacerbation with urinary frequency, urgency, dysuria, costovertebral pain, chills and fever. During the last year he had been treated with mandelic acid, frequently with ureteral irrigation, and more recently with protargin. In spite of this prolonged infection, the only significant signs of renal failure were a persistently low specific gravity and a large urinary output. There had been no enlargement of the heart, and the blood pressure had remained normal. He had had coronal ulcers and a persistent dermatitis which were attributed to the presence of chronic infection.

Dr. Quinby commented on the extreme difficulty of treating these cases. He stated that the course was invariably downhill. He also noted that loss of power of concentration of the urine was often the first indication of renal failure.

The second case was presented from the medical service by Dr. McClure. The patient was a 41-year-old female. Six years before entry she was found to have bilateral renal stones. She developed a left perinephric abscess

which was drained on the surgical service. In spite of this drainage there were severe exacerbations of pain, and chills, and 4 months later a left nephrectomy had been done. Removal of the renal stone on the right was not attempted because of poor renal function. One year after this she was found to have hypertension and elevated blood urea nitrogen. Pus was found regularly in the urine. Two years before her final admission she developed angina pectoris and this had increased in severity. Her symptoms of uremia and of secondary anemia increased, she lapsed into coma and died.

The pathological findings in the two kidneys were compared by Dr. Ayer. The kidney removed in 1932 weighed 120 gm., that at autopsy 60 gm. Both showed a marked pyelonephritis. In addition, the kidney removed at autopsy showed marked vascular lesions, which were not present in the specimen removed in 1932.

Dr. Soma Weiss presented the paper of the evening. He first reviewed Bright's classification of nephritis and then called attention to the lack of emphasis which, until recent years, had been placed on the group originating as bacterial infection of the kidney. The attention of himself and of Dr. Frederick Parker, Jr., had first been called to this group by the finding that certain cases which had been diagnosed as essential hypertension could be explained as the end results of pyelonephritis. He then drew certain generalizations. Pyelitis as such probably does not exist. The infection, whether it be hematogenous, ascending or spread by way of the lymphatics, very soon becomes distributed throughout the pelvis and throughout the adjacent renal tissue so that the root of origin cannot be determined by pathological examination. Furthermore, the presence of the infection in the interstitial tissue and in the lymphatics enables kidneys which show no clinical evidence of infection still to be the seat of an active infectious or inflammatory process. These changes were illustrated by lantern slides. In a similar way he went on to show how kidneys which are the seat of chronic infection gradually become scarred and shrunken. This latter process can advance after the infection has disappeared. In addition to actual destruction of the glomeruli there frequently is considerable tubular destruction by blockage from below. Furthermore, vascular changes are superimposed. The presence and the extent of these changes seem to depend on how the patient reacted to his renal damage by an arterial hypertension. The changes in the arterioles themselves are usually of the hyperplastic arteriosclerotic type. They are also analogous to those changes found in the pulmonary arteries of cases of mitral stenosis in which there has been a severe degree of pulmonary hypertension and circulatory stasis. Thus the vascular changes are dependent upon the hypertension but not entirely so, for inflammation in the kidney itself apparently has a direct effect upon the arterioles. This is best illustrated by cases of unilateral pyelonephritis. In these the arteriolar changes are definitely more marked in the affected kidney than in the normal kidney. Areas in the same kidney where the inflammation is more pronounced also show less arteriolar change than less inflamed areas in the same kidney. Just as in essential hypertension, the so-called benign and malignant types of arteriolar change are found. Their presence apparently depends on the height and rate of progression of the hypertension. Pyelonephritis is responsible for about 15 or 20 per cent of the instances of the malignant phase of hypertension. Dr. Weiss called attention to the frequency of pyelonephritis and pointed out the importance of an understanding of this condition in the fields of surgery, pediatrics, obstetrics and internal medicine. Because of the close rela-

turity, might not survive after delivery. Because of these factors, a low vertical cesarian section was performed on October 11. The placenta was centrally implanted, covering the entire os. A female child weighing 3 lb. was delivered and lived only a few hours. The patient's convalescence was normal.

On the seventh postpartum day a blood count showed 3,250,000 erythrocytes with a hemoglobin of 68 per cent (Sahli) and 7000 leukocytes with a normal differential. The patient was discharged on October 27, the sixteenth postpartum day, in good condition.

Comment. The delivery of this patient, when the chance of a viable child was questionable and in the absence of bleeding, is open to criticism. Had this patient been kept in bed in the hospital in the hope that no bleeding would occur until the baby's chance of survival was assured, it is quite likely that a viable baby would have been obtained. It is true that, at any minute, brisk hemorrhage might have necessitated operation. Under those circumstances, the operation would have been undertaken for the sake of the mother because of active bleeding, irrespective of the result on the child. The danger to her from a recurrent severe hemorrhage, occurring while she was in the hospital where delivery could be consummated within an hour, was negligible, and if a period of two weeks could have elapsed before another hemorrhage, the baby probably would have lived. There is a difference of opinion about performing a low cervical cesarian section in cases with placenta previa. Some feel that in placenta previa, because of the possibility of increased hemorrhage, there is a contraindication to low section. At any rate, an abdominal section for placenta previa on a patient who is bleeding and not in labor, after the point of viability of the fetus, is becoming generally accepted as the more conservative method of treatment.

MISCELLANY

DEATH OF DR. LAWRASON BROWN

In the death of Dr. Lawrason Brown at Saranac Lake, New York, on December 26, the profession has lost one of its foremost tuberculosis specialists. He had been actively connected with the Trudeau Sanatorium for nearly forty years, and was particularly prominent in the development of the Trudeau School of Tuberculosis, in which many physicians have received unexcelled instruction in the diagnosis and treatment of tuberculosis. He was a pioneer worker in intestinal tuberculosis and was among the first to adopt roentgenologic findings as a means of classifying pulmonary lesions.

He had been an associate editor of the *American Review of Tuberculosis* for many years. He was a member of the

American Association of Physicians and a past president of the American Climatological Association, the National Tuberculosis Association and the American Sanatorium Association.

CORRESPONDENCE

FOOD, DRUG AND COSMETIC CONTROL

To the Editor. Physicians in New England have an opportunity to give valuable help in securing better laws on pure food, drugs and cosmetics and their advertising. To find out why there is need for betterment read the editorial "When to Lock the Stable" in the December 9 issue of the *New England Journal of Medicine*. The Secretary of Agriculture at Washington says: "Electricians, plumbers and steam engineers pursue their respective trades under license. But there is no such control to prevent incompetent drug manufacturers from marketing any kind of lethal potion." Why?

The *Literary Digest* of December 18, 1937, answers as follows: "Thus it is amazing to note that today tens of thousands of physicians, the country over, are embattled concerning the development of novel government agencies for socializing medicine—before they have moved note worthily toward lifting a natural government function to a wise and effective plan. This 'lift' is tragically needed. Our government drug regulations and their enforcement are still on the plan of moronic farce."

How can we answer this challenge? By writing today, each of us, to our two United States Senators, to our local representative in the House of Representatives at Washington and to Senator Royal S. Copeland and Representative Clarence F. Lea, chairmen of the two committees studying needed legislation. Say in such a letter that you wish better control of food, drugs and cosmetics by a law that provides for labels stating their composition in full with warnings as to dangers in their use, that prevents distribution of drugs and cosmetics before they have been tested as to toxic action and that prevents general distribution to the lay public of drugs which, if used indiscriminately, might be dangerous, all to be enforced by the Food and Drug Administration of the United States Department of Agriculture, and that you wish restriction on all false and misleading advertising of these products by a strong law with penalties to be administered by the Food and Drug Administration so that there will be no divided responsibility.

Do this yourself and do it today. Then when your local medical society meets have it adopt resolutions expressing these ideas and send them to those already mentioned.

A medical profession that does nothing toward better laws for pure food, drugs and cosmetics is assuming responsibility for other deaths likely to occur under present laws. That people have died from using Elixir Sulfanilamide in recent months is a challenge to physicians. Remember that powerful interests in the drug and food trades fight against restrictive laws, they are well organized, so there is great need that every physician express himself to those who make our laws in Washington.

BOSTON SOCIETY OF ANESTHETISTS

The next meeting of the Boston Society of Anesthetists will be held on Tuesday, January 25, at the Hotel Kenmore.

PROGRAM

Dinner 6 30 p. m.

Business meeting. Election of officers 7 40 p. m.

Scientific meeting 8 15 p. m. Dr Soma Weiss will speak on 'Preanesthetic and Postanesthetic Problems from the Point of View of the Internist.'

Physicians and medical students are cordially invited to attend.

ELEANOR B. FERGUSON, M.D., *Secretary*

THE MASSACHUSETTS SOCIETY FOR SOCIAL HYGIENE

The Massachusetts Society for Social Hygiene is sponsoring an open meeting at Ford Hall, 15 Ashburton Place, Boston, Thursday evening, January 20, at 8 15

Dr Stanley H. Osborn, commissioner of health of the State of Connecticut, will speak on 'The Connecticut Blood Test Before Marriage Law,' and will describe its genesis, its provisions and the way in which it has so far worked out.

Dr Nels A. Nelson, director of the Division of Genito-infectious Diseases of the Massachusetts Department of Public Health, will discuss Dr Osborn's paper. Dr Nelson is opposed to such legislation and the meeting will thus give an opportunity for those who attend to hear both sides of this important question. There will be opportunity also for open discussion from the floor.

This meeting will be of particular interest to physicians, legislators, social workers and other professional workers. The meeting is open to the public and a cordial invitation is extended to all who are interested. There will be no admission fee.

TUFTS MEDICAL ALUMNI CLUB OF WORCESTER COUNTY

There will be a meeting of the Tufts Medical Alumni Club of Worcester County at the Bancroft Hotel, Worcester, on Wednesday, January 19. Dinner at 6.30 p. m. will be followed by a business meeting at 7.30 p. m.

Dr Henry W. Hudson, Jr., will speak on 'Conceptions and Misconceptions of Surgery in Infancy and Childhood.'

C. BYRNE, M.D., *President*,
N. S. SCARCELLO, M.D., *Secretary*

LECTURES AT THE FAULKNER HOSPITAL

A series of illustrated, public, health lectures at the Faulkner Hospital will be held in the hospital auditorium at 4 p. m. on Sundays. The schedule is as follows:

January 16—Heart Ailments and Their Prevention. Dr Burton E. Hamilton.

January 23—Common Colds and Their Prevention. Dr James A. Halsted.

January 30—Skin Evidences of General Ill Health. Dr E. Lawrence Oliver.

February 6—Practical Hints for the Expectant Mother (women only). Dr D. J. Bristol, Jr.

February 13—Stomach and Duodenal Ulcer. Dr Edward S. Emery, Jr.

February 20—Progress in Dental Surgery. Dr Kurt H. Thoma.

February 27—Backache. Dr John D. Adams.

March 6—Chest Operations in the Treatment of Tuberculosis. Dr Harlan F. Newton.

March 13—Diets and Vitamins in the Preservation of Health. Dr Maurice B. Strauss.

March 20—Diseases of the Prostate Gland (men only). Dr Franklin Balch, Jr.

March 27—Hay Fever and Asthma. Dr Walter S. Burrage.

April 3—Nerves and Their Relation to Insanity. Dr Merrill Moore.

April 10—Common Foot Ailments and Their Significance. Dr Lloyd T. Brown.

April 24—Syphilis: Its cause, prevalence and eradication. Dr Channing Frothingham.

tion of pyelonephritis to arterial hypertension of renal origin and to the small contracted kidney, pyelonephritis should be considered as one type of Bright's disease. The close interrelation between the various types of Bright's disease was emphasized.

Dr Christian in discussing the paper made a plea for a more simplified classification of Bright's disease. He advocated a division into (1) acute stage, (2) subacute or chronic stages with edema, and (3) a chronic stage with out edema. This last stage, as characterized by small shrunken kidneys, can be reached either by essential hypertension with vascular change, by glomerular damage, by infection, or even by primary tubular damage as in nephrosis.

NOTICES

REMOVAL

DAVID KUNIAN, M.D., announces the removal of his office to 19 Nahant Street, Lynn.

CAMBRIDGE HOSPITAL

The regular monthly meeting of the staff of the Cambridge Hospital will be held in conjunction with the Middlesex South District Medical Society in the lecture hall of the nurses' home at 10 00 a. m., January 19.

A clinicopathological discussion will be held. A buffet luncheon will be served at 1 00 p. m.

Please notify the director if you plan to attend.

JOSEPH M. WADDEN, M.D., *Secretary*

TUMOR CLINIC, BOSTON DISPENSARY

Each Tuesday and Friday morning from ten to twelve thirty there is a meeting of the Tumor Clinic of the Boston Dispensary, a unit of the New England Medical Center. All kinds of tumors are seen, discussed, and when indicated, treated with radium and high-voltage x-ray.

Physicians are welcome to visit this clinic and to bring a patient to the clinic for diagnosis.

HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held in the Peter Bent Brigham Hospital amphitheater (Shattuck Street entrance), Tuesday, January 25, at 8 15 p. m.

PROGRAM

Presentation of cases

Medical Investigations in Peru in 1937. Drs. Richard P. Strong, Henry Pinkerton, and David Weinman.

Medical students and physicians are cordially invited to attend.

MARSHALL N. FULTON, M.D., *Secretary*

JOINT MEETING OF THE SUFFOLK DISTRICT MEDICAL SOCIETY AND THE BOSTON MEDICAL LIBRARY

There will be a joint meeting of the Suffolk District Medical Society and the Boston Medical Library at the Boston Medical Library, 8 Fenway, on Wednesday, January 19, at 8 15 p. m.

The "Principles and Proposals" will be discussed by the following: Dr. Robert B. Osgood, Dr. Frank H. Lahey,

Dr. Channing Frothingham, Dr. Elliott P. Joslin, Dr. Richard M. Smith and Dr. Roger I. Lee.

JOHN P. MONKS, M.D., *Secretary*
Suffolk District Medical Society

JAMES M. FAULKNER, M.D., *Secretary*,
Boston Medical Library

CARNEY HOSPITAL

The monthly clinical meeting and luncheon of the Carney Hospital Staff will be held on Monday, January 17, in the Andrew Carney Assembly Hall, at 11 30 a. m.

PROGRAM

Case reports

Epidural Cyst with Removal and Recovery
Polycythemia

Carcinoma of Cervix Treated with Radium. Subsequent Removal of Rapidly Growing Ovarian Tumors.

Pathological exhibit.

Determination of Blood Loss in Certain Standard Operations for Malignancy. Dr. Weston Buddington. Discussion by Drs. A. Fraser, William C. Moloney and Roy J. Heffernan.

Physicians and students are cordially invited to attend.

ROY J. HEFFERNAN, M.D., *Secretary*

GREEN LIGHTS TO HEALTH

The following change in the "Green Lights to Health" broadcast, being given over Station WAAB at 7 30 p. m., on Wednesdays, has been announced. Dr. Elliott S. Robinson will speak on January 19. His subject will be "The Laboratory Fights Pneumonia."

BOSTON MEDICAL HISTORY CLUB

There will be a meeting of the Boston Medical History Club at the Boston Medical Library, 8 Fenway, on Monday, January 17, at 8 15 p. m.

Dr. Donald S. King will talk on "The Development of Our Knowledge of the Lung and Its Diseases."

BENJAMIN SPECTOR, M.D., *Secretary*

NEW ENGLAND SOCIETY OF PHYSICAL MEDICINE

The regular meeting of the New England Society of Physical Medicine will be held at the Hotel Kenmore, on Wednesday evening, January 19, at 8 00.

PROGRAM

Some Fundamental Types of Physical Medicine and Their Practical Application. Dr. Franklin P. Lowry. Demonstrated by Miss Esther Klein. Discussion—Dr. Howard Moore.

The council will meet at 6 00, dinner will be served in the Empire Room at 6 30.

All members of the medical profession are cordially invited to attend.

WILLIAM D. MCFEE, M.D., *Secretary*

THE NORFOLK DISTRICT MEDICAL SOCIETY

The regular meeting of the Norfolk District Medical Society will be held in the Hotel Kenmore, on January 25, at 8 15 p. m. Tel. Ken 2770.

NUMBER 3

BRONCHIECTASIS

Physical and Psychologic Manifestations

EDWARD D. CHURCHILL, M.D.*

BOSTON

WHEN the operative mortality of lobectomy for bronchiectasis was at least 50 per cent and the results in many survivors uncertain or imperfect, a cautious attitude in advising the operation was understandable. At the present time, however, we are privileged to report a mortality rate of 47 per cent in a series of 84 cases with lobectomies for bronchiectasis. This includes all cases in which the operation has been done or attempted. What is even more encouraging, only 1 death has occurred in the 66 unilateral lobectomies performed in the past four years, giving an operative mortality of 1.5 per cent. This death occurred as the result of Type III pneumococcus pneumonia and pericarditis ten months after operation, in a patient who had been discharged from the hospital. As a residual empyema cavity was still present and may have been a contributing factor, the death is recorded as an operative mortality. In 6 cases of bilateral disease a lobectomy has also been carried out on the second side. There has been 1 death among these 6 cases, attributable to bronchiectasis in the remaining upper lobes.

All the patients who have survived have been greatly helped by the operation, and about 85 per cent have been entirely cured. The operation causes no noteworthy deformity. With rare exceptions, operative incisions and bronchial fistulas heal within a few weeks. There is only one persistent bronchial fistula in our entire series—the first patient operated upon by a method now abandoned. These statistics give an entirely new status to the operation of lobectomy, and stand as a challenge to the physician who refers to surgery in bronchiectasis as a last resort. The indications for recommending lobectomy must be redefined on the basis of a careful evaluation of the symptoms of the disease.

Only a close acquaintance with a number of patients in all stages of the disease, not only before but after the operation, gives a conception of the profound effect bronchiectasis may exert upon the life of an individual. It is not necessary to dwell upon the suffering produced by gross forms of the disease. Patients with profuse foul sputum have long been referred to as social outcasts. The effects of the so-called "milder" forms of bronchiectasis must be evaluated now that it is practical to extend the indications for operation. Members of the medical profession are apt to call bronchiectasis mild if the patient appears to be in a state of good nutrition, and if the sputum is not offensive enough to drive other patients from the waiting-room.

Bronchiectasis, severe or mild, is a disease of youth and early adult life, and exerts its influence on both body and mind during the formative period—an age in which social contacts are established, personality is crystallized and foundations for life's work are laid. Handicaps and physical limitations, which a mature individual might integrate or compensate for, produce an intense effect during these important years.

A productive cough is usually the presenting symptom. It may in itself cause distress and inconvenience to the patient, and almost invariably renders him sensitive to its effect upon others. He is reluctant to appear at social gatherings or to attend the theater. Even a trip in the subway may prove disastrous unless a patient can calculate when his next "emptying time" is due. A spell of coughing is apt to be induced by laughter, alarming other people and causing the patient acute embarrassment. The result in a sensitive individual is a tendency to shun social contacts. Invitations are refused. The sufferer becomes increasingly shy and solitary. Parents and the immediate family may be sympathetic and tolerant, but others are oftentimes cruel and ruthless. Casual friends and classmates, having no insight into the state of af-

John Homan, Professor of Surgery, Harvard University; chief of the West Surgical Service, Massachusetts General Hospital.

NEW ENGLAND PATHOLOGICAL SOCIETY

There will be a meeting of the New England Pathological Society in the large amphitheater of the Children's Hospital on Thursday, January 20 at 8 00 p m

Dr C P Rhoads, Rockefeller Hospital, New York, will speak on 'The Pathologic Morphology and Physiology of Refractory Anemia'

Physicians and medical students are cordially invited to attend

J B HAZARD M.D., *Secretary*

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY, JANUARY 17

MONDAY JANUARY 17

- *11 30 a m Carney Hospital clinical meeting Andrew Carney Assembly Hall.
- 8 15 p m Boston Medical History Club Boston Medical Library 8 Fenway

TUESDAY JANUARY 18

- 9 10 a m Boston Dispensary Types of Hemolytic Anemia Dr William Dameshek
- *10 a m 12 30 p m Tumor clinic Boston Dispensary
- *12 m South End Medical Club Headquarters of the Boston Tuberculosis Association 554 Columbus Avenue, Boston

WEDNESDAY JANUARY 19

- *9 10 a m Boston Dispensary Clinicopathological conference Dr R. C. Wadsworth Dr Robert W. Buck.
- *12 m Clinicopathological conference Children's Hospital Amphitheater
- *8 p m New England Society of Physical Medicine Hotel Kenmore Boston

THURSDAY JANUARY 20

- 8 30 9 30 a m Exchange visit surgical and orthopedic staffs of the Peter Bent Brigham and Children's hospitals held this week at the Children's Hospital
- *9 10 a m Boston Dispensary Recent Advances in the Treatment of Pulmonary Tuberculosis Dr M H Holden
- *8 p m New England Pathological Society Amphitheater of Children's Hospital
- 8 15 p m Boston Society of Psychiatry and Neurology Boston Medical Library 8 Fenway
- 8 15 p m Massachusetts Society for Social Hygiene Ford Hall 15 Ashburton Place Boston

FRIDAY JANUARY 21

- 9 10 a m Boston Dispensary Here and There in Endocrinology Dr Pulcr Albright
- *10 a m 12 30 p m Tumor clinic Boston Dispensary
- 12 m Clinical meeting of the Children's Medical Service Massachusetts General Hospital Ether Dome

SATURDAY JANUARY 22

- 9 10 a m Boston Dispensary Hospital Case Presentation Dr Samuel H. Proger
- 10 a m 12 m Staff rounds at the Peter Bent Brigham Hospital Conducted by Dr Henry A. Christian

SUNDAY JANUARY 23

- 4 p m Free public lecture Harvard Medical School amphitheater of Building D Teeth Deciduous Permanent and Artificial Dr Paul E. Boyle
- 4 p m Free public lecture Beth Israel Hospital Boston in conjunction with the Women's Auxiliary What to Do About Cancer Dr Harry P. Friedman
- 4 p m Illustrated public health lecture, Faulkner Hospital Common Colds and Their Prevention Dr James A. Halsted

- FEBRUARY 9—Worcester State Hospital Worcester
- MARCH 9—Memorial Hospital Worcester
- APRIL 13—Hahnemann Hospital Worcester
- MAY 11—Afternoon and evening annual meeting Place and schedule of program to be announced.

It may appear that I have drawn too harsh a picture of what is called mild bronchiectasis. It is true that many patients are able to make an admirable adjustment to the disease. The description has been compiled, however, directly from case histories. Members of the lower mental strata naturally offer fewer psychologic problems or are inarticulate concerning them. Nearly every patient will discuss these aspects of the disease more freely after the operation has been completed. This is because a closer relation with the surgeon has been established during the emotional crisis of the operation, and because when freed of the disease the patient's struggle with it comes to the surface.

In determining indications for operation in the given case, the physician must have insight into these subtler aspects of the malady. It is impossible to measure the severity of bronchiectasis by the number of cubic centimeters of sputum in the cup or by the foulness of the breath. The mere fact that a patient is able to work or attend school is not a safe criterion of his happiness. The effect of the disease on the personality of the patient and on his life as a whole must be taken into consideration.

It is particularly important that bronchiectasis be recognized and adequately treated early in life, in this way serious psychologic difficulties and personality changes may be avoided. Patients between the ages of five and twelve stand the operation admirably. Young adults should be operated on before they assume the social responsibilities of marriage, or before the door to a happy marriage is closed to them by their illness.

The following case records are typical of the stories that can be obtained from patients with bronchiectasis. They express better than any description the actual nature of the disease.

CASE REPORTS

Case 1 I. E., a 25-year-old woman, had extensive bilateral disease dating from pneumonia in childhood. A great deal of her schoolwork was done at home, causing her to miss the social life of her schoolmates. She completed her college education, but devoted all her limited energy to actual study. While taking vocational courses she was frequently told, "Your work is excellent, but your health is so poor we cannot recommend you for a position." She continually felt that she was "obnoxious to people, despite the fact that the sputum was foul only at intervals. Because of this, she disliked having a roommate. On several occasions older girls at college took her to task for the cough, telling her that if you tried harder you would cough less."

She was examined yearly for tuberculosis, and in the middle of her second college year was sent home because she was "in the last stages of tuberculosis." An experience that almost proved to be a catastrophe happened in her last college year. She fainted in a classroom, and while she was unconscious a large amount of sputum poured out on the floor. Her embarrassment would have caused her

to leave school if she had not been within two months of completion of the course.

A very intelligent mother trained in educational and social work has been able to handle the problems of adjustment in an admirable way. The girl was never held back, but urged to enter sports and other activities up to the limit of her endurance. A close circle of family friends provided an enjoyable social background. The most difficult period of adjustment was between the years of 14 and 18.

Although emotionally well adjusted to her handicap she presented herself at the age of 25, realizing that her symptoms were steadily becoming worse. Employment in the fields in which she had struggled for an education was closed to her. Thoughts of marriage had long been thrust out of her mind. When the dangers and discomforts of a bilateral lobectomy were outlined they were accepted cheerfully and without fear. The courage and philosophy gained through years of suffering have carried her through successfully.

Case 2 K. B., a 5-year-old boy cannot be expected to have insight regarding his disease or even to give a coherent account of symptoms. The objective signs of the disease were minimal. Fortunately a very intelligent mother realized that the child's activities were limited by the disease and a lobectomy was performed. Four months after the operation, when the boy had gained 12 lb in weight and showed a corresponding gain in strength, Mrs. B. commented as follows: "My neighbors did not understand how I could give my consent to such a dangerous operation because they thought K. was perfectly well and could run and play like the other boys, but I knew he was not well, and the great change after the operation certainly proves it."

Case 3 H. S., at the age of 23, is a confirmed hypochondriac. His father is a well-to-do manufacturer who has done everything possible for the boy's welfare. The disease began in childhood. Three years were spent in the Southwest. Cough and sputum were never excessive, but constant fatigue and its resulting lack of ambition colored his personality. He was desperately afraid of tuberculosis. It took this young man considerable time to summon courage to face the operation. The influence that turned the tide was a chat with a cured patient.

Fortunately the convalescence was smooth and uneventful. Even so, the patient imagined every possible complication. It is doubtful whether he will completely overcome his neurotic tendencies, even though the organic basis has been removed. A lobectomy early in life might well have prevented the development of this abnormal personality.

Case 4 The experience of A. L., a 28-year-old man, proves the value of our admonition that bronchiectasis should receive adequate treatment before marriage or other social responsibilities are undertaken. He suffered very little from his bronchiectasis during his bachelor days. He completed his education and held a good position as sales manager in a large company. On return from work he would lie down for an hour's rest before dinner. Three evenings a week were spent in a gymnasium. He was an expert tennis player.

He married an attractive girl whose home was in a distant city. Taking up her home in a strange place, she naturally leaned heavily upon him for entertainment. He began to make long automobile trips in order to get home for dinner. The pair would frequently go to bridge parties or to the theater in the evening. Although the

fairs, are critical, and are prone to suggest that the cough is an annoying habit which the patient could control if he tried to do so

Bronchiectasis is characterized by acute pneumonic episodes initiated by respiratory infections, particularly during the winter months. The acute infections interrupt progress in school or cause loss of time from work.

In the intervals between acute attacks, the smoldering infection in the lung or the retention of pus in the dilated bronchi may give rise to a sense of fatigue that is insidious and vicious in its effects. When this has persisted for years a patient may accept it as a normal state of affairs, and may become aware of his limitations only when relieved by cure. On the other hand, he may be totally unable to work, or if he can work, the routine of the day absorbs all available energy so that he has little ambition to undertake other activities. One patient remarked that she was always glad to get home from school just to rest. Many are unable to keep up with their schoolwork.

The lack of physical endurance paralyzes plans and ambitions for a future career. Over and over again patients confess that they had wanted to take up certain vocational training, but realized that they lacked the physical energy to see it through.

The confusion with pulmonary tuberculosis because of the cough, sputum and hemorrhages raises important psychologic conflicts. When a person develops pulmonary tuberculosis he usually faces the facts, and after a more or less stormy period of adjustment develops a philosophy concerning his disease. I do not wish to imply that the psychologic problems of tuberculosis are simple ones, but they can be faced as a more clean-cut problem. In many respects it is better to have tuberculosis outright than to be constantly suspected of having it. The external world is more understanding and sympathetic if a definite label can be affixed to a complaint. Tuberculous patients find companionship in the fraternity of this disease. Nearly all my patients with bronchiectasis have been fearful of or sensitive about tuberculosis. One girl was sent home from college in the middle of her second year because she was "in the last stages of consumption." Many others have been unable to hold steady employment because fellow employees became alarmed about their cough. One patient sought out-of-door employment on a milk route, with the result that complaints came from customers who feared that he had tuberculosis.

Hemorrhages are frequent occurrences in bronchiectasis, and are always very disturbing to the patient. Again, a patient with tuberculosis accepts a hemorrhage as a natural event in the course of

his disease. He knows of other patients who have had similar occurrences, and is not unduly alarmed. The hemorrhages in bronchiectasis instill the terror of the unknown. They may be so frequent and so severe as to incapacitate the patient over long periods of time. Sanatorium care is often prescribed for hemorrhage mistakenly diagnosed as evidence of tuberculosis.

The menstrual cycle is frequently disturbed by the chronic invalidism of the disease. Scanty and irregular flow with delayed adolescence appears to reflect the general state of ill-health. In a patient with bilateral bronchiectasis, regular and normal menstruation was established for the first time in her life at the age of twenty-seven after bilateral lobectomy. Menstruation prior to this time had occurred only at irregular intervals of several months.

Young women with bronchiectasis usually consider themselves unfit to bear children. This impression may be obtained directly from their medical adviser, or may find origin in the remarks of friends and relatives.

Patients with basal bronchiectasis find that the exertion and posture of sexual intercourse provoke coughing and expectoration. If the sputum is foul the results may be peculiarly embarrassing.

If the symptoms of bronchiectasis are at all severe, the patient early becomes aware of the impossibility of getting married. This rarely presents itself as an acute psychologic problem, as the limited social contacts lead to this conclusion insidiously but inevitably. Patients are rarely willing to admit that this is a problem, but when the doors both to marriage and to a career of choice are closed, the future appears to hold little promise for any young person.

Young adult patients rarely hesitate to elect a chance of cure if the possibility is offered. In spite of the mortality statistics already referred to, the operation of lobectomy has always been presented to the patient as a serious affair. In the few instances in which operation has been refused, the negative reaction has been due to prejudice, low-grade mentality or pressure from outside sources. Unfortunately, we still see the patient who returns to his family doctor for advice and is told that the operation is an impossible one and that to consent to it means certain death. Having in mind certain extensive operations that have been necessary in neglected cases of chronic empyema, the uninformed doctor pictures the horrible deformities that result from thoracic surgery.

As a matter of fact, there is rarely any deformity whatsoever following lobectomy. If desired, the operation can be performed through an intercostal incision without even the removal of one rib.

At the university clinic I was told that I had asthma, owing to the fact that I was allergic to many different foods, plants, and so forth. For 1 of the 2 years there I was put through a desensitization process, which was very tedious and brought no good results.

When I returned to the state hospital, — this time in the social service department, — I was very glad to tell people at last what it was that ailed me. Until this time I had thought that no one in the world had ever had a condition like mine. But the remedy seemed worse than the disease, so I did nothing about serums or cutting out all the foods that I was told to. Even a slight attack of asthma was enough to depress me, and send me almost into a panic. It would make me feel as though I were going to be a semi-invalid all my life, and the future looked very black. As soon as the attack was over I lost this fear.

I began to read about asthma having an emotional basis, and had plenty of encouragement to think along this line from various psychiatrists I knew. For a year I had analytic therapy, which did not, however, change my physical condition, unless possibly indirectly by helping me to become somewhat more mature emotionally.

During the 5 years after I had left the West I did not consult any doctor (except that I always saw our family physician at various times and frequently had physiotherapy and other general treatment from him). I really felt that the doctors would have nothing to offer. I still thought that somehow my troubles might all be on a psychologic basis. I knew I was unhappy because of my restricted social life, my failure to marry, and so on. I wanted children, yet it seemed as though I had no right to have them. I had been told, too, that with my cough I should probably be unable to carry a child. All this meant that I should have to remain a social worker, and I wasn't even sure I could manage that. I should be expected to go on to more responsible, demanding positions. Even now I have to go to many meetings where the old problem comes up. Last year, after a series of meetings, one social worker spoke to me about it, and said I certainly sounded as though I were in the last stages of tuberculosis.

Early last summer I was coughing unusually hard and had some pain in my chest. I felt that I could not go on any longer, and was ready to give up my work and go to Arizona or its vicinity. Someone persuaded me to consult a specialist first.

N B. There are various reasons why my social life has been restricted. Many things are too strenuous for me even to attempt. The fact that I require more rest than most people made it necessary for me to cut down somewhere, and I couldn't do so in my work. Unless you are always ready to do things, people get out of the habit of including you. At the theater and the symphony coughing disturbs other people.

Case 6. M. J., a 42-year-old man, displayed quite a different reaction to the disease. His cough dated from early childhood. At the age of 14 or thereabouts he chanced on some correspondence concerning his illness, between his mother and a patent medicine company. He learned that he had tuberculosis and Bright's disease. Shortly thereafter he overheard the family doctor assuring his mother that he would 'be dead at 17, whatever was done for him. His response was the fatalistic 'what the hell' attitude. As his illness was going to get him and he was doomed to die anyway, he decided to enjoy life while he could.

He took up the life of a wanderer and hobo. In a lumber

camp in the Rocky Mountains he cut a trap door by the head of his bed for convenience in expectoration. On the prairies of northwestern Canada he was made to sleep in a separate shack because fellow workmen feared tuberculosis. During the World War he tried desperately to suppress his cough while on a night scouting expedition in no man's land. Unable to keep from coughing, he was sprayed by machine gun fire and barely escaped with his life.

He finally ceased his wandering when he found the disease was not incompatible with life, and married. He now works steadily as a plasterer, but during the past 2 years he has noticed a steady increase in shortness of breath and a lack of endurance.

By adopting a casual and 'hard-boiled' attitude toward the disease, he altered the course of his whole life, but protected himself from the embarrassment caused by specific symptoms. His cough and expectoration have not kept him from social contacts or marriage. Looking backward, he regrets that he did not settle down to a good trade which was open to him at 18.

This attitude is frequently encountered in young boys, but is rarely projected into adult life as in this patient, the fact that his sputum was not foul enabled him to play his role with success. A similar attitude is well expressed by the patient in Case 5, who spit for the other children and told them it was 'poison'. It usually collapses with adolescence, when contacts with the opposite sex become desirable.

Case 7. L. D., a young man, aged 17 years, had steady employment in a butcher shop in a small New England town, he found that the copious and very offensive sputum coming from a bilateral basal bronchiectasis absolutely prevented him from forming friendship with girls. He came to Boston ready to accept any risk to be freed of his disease. A bilateral lobectomy has left him with no cough and no sputum.

CONCLUSIONS

Experience in the study and treatment of bronchiectasis has led me to two conclusions. First, established bronchiectasis is not a self-limited disease but a persistent and often progressive malady, constituting even in its milder forms a serious physical and psychologic handicap to the patient and eventually terminating in death. Secondly, while postural drainage, bronchoscopic drainage, change of climate, operations on nasal sinuses, phrenic-nerve paralysis, artificial pneumothorax, thoracoplasty, x-ray treatment, lipiodol instillations, injection of arsenicals, vaccine therapy and a host of other so-called remedies may in certain instances bring gratifying symptomatic relief there is no real cure but extirpation of the diseased segment of lung.

Fortunately, the time has arrived when the medical profession can stop fumbling with bronchiectasis and approach its treatment by a direct, effective and safe form of therapy. A physician shoulders a grave responsibility when his advice withholds the benefits of surgery from a young patient suffering from this disease. Operation can no longer be termed a measure of last resort.

man had always considered himself physically fit for any thing, the pace began to tell, and the disease flared up with an attack of pleurisy. He began to feel tired, and wanted to stay home and rest in the evening. Rather than face the situation frankly with his wife he assumed a defensive attitude, becoming irritable and uncommunicative. When he became affectionate he would suddenly turn away to conceal a cough, and would find his action misinterpreted. He tried to conceal his illness from his wife and her family, feeling that he would be blamed for having married in the knowledge that he had had his disease for years. As a child, he concealed his cough by saying that he was sick to his stomach, now he concealed his cough from his wife by turning on the faucets in the bathroom.

Matters went from bad to worse, within 10 months of the marriage the wife was in tears and returned to her home, and the patient was anxiously seeking a cure for his disease at any risk. A careful study of the situation made it probable that the disease was the primary element and the marital difficulties secondary, so that lobectomy was undertaken. The patient's defensive attitude was carried through the operation and into convalescence, he tried to conceal the fact that he was undergoing a serious operation for a condition that was present before his marriage. After his complete recovery the whole situation was talked over with both him and his wife. They are now trying to make a new start in their married life.

Case 5 A. P., a 32 year-old woman, wrote the following account, entitled *How Bronchiectasis Has Affected My Life*.

My cough I have had with me daily since I was 4 years old. I don't know just what it meant to me when I first had it. I remember my mother's hovering over me at night, bundling me up in the winter, and even in the summer telling me to stay in the sun, I knew my playmates did not have to do this. I also remember a group of teachers in the primary school calling me over and asking me about it, I think I was pleased with the attention but did not know what to say. I used to spit for the other children and tell them it was poison.

A few years later I began to get irritable with my mother. Every time I turned around there was a spoonful of cough medicine waiting for me. I openly rebelled against it all and could not be trusted to take the medicine. It may have been this situation that led my mother to suspect me of being deliberately careless about rubbers, gloves, buttoning my coat, and so forth. All this was a bone of contention between us. My mother commented frequently on the change in my disposition, and there grew up a legend about my former good naturedness.

I now know from stories my mother has told me, and from my own experience as an adult, that her life was considerably upset by friends and relatives. Half of them took my cough very seriously and may have been critical of her for it, and the other half said it was nothing and were disgusted with the attention she paid me. When I had attacks of bronchitis or pleurisy, she always cried and thought I was going to die, but I can't recall that I had any such fear.

"During this period (roughly from 9 to 12) I grew to be annoyed with anyone else who drew my attention to it. The whole thing was a nuisance to me. I was advised by an aunt never to laugh because it would aggravate the cough, and many people told me they couldn't tell the difference between my laugh and my cough. My music teacher used to compare my cough with one she had had before she went to Canada for treatment for tuberculosis. I had great respect for her, but I was somewhat indignant

that such a comparison should be made. When someone would say, 'You have a cold all the time! I would reply crossly, 'It isn't a cold!' But I couldn't tell them what it was, and I felt very foolish. All the doctors I had been to had never given a name to it, they had only assured my mother that I would outgrow it.

By the time I went to high school I had developed a sinus infection that certainly completed the picture of a cold all the time. I had plenty of girl friends who were used to me as I was and accepted me, so that I had a happy enough time with them, but I did not go on to the new things—organized sports and friendships with boys. I had grown very self-conscious and was afraid of comments. When any were made, I passed over them as quickly as I could, no longer insisting that I did not have a cold. The classes were 50 minutes long with 10 minutes between, and this used to help me, because in the interval I could go off by myself and cough all I wanted to. Long meetings in the assembly hall were a problem, however, and I sometimes begged off, but I couldn't do it often because the instructors began questioning me. While I was still in high school I went to another city as a delegate to a conference. At one of the meetings, which was long, I became quite choked up and began to cough a good deal. I tried to stifle it and apparently the result was funny, because it made a group of girls laugh, and afterward the leader asked me what those queer sounds were that I had made. This particular experience was unusually humiliating. My family did not object when I stopped going to church after one of the members of the congregation loudly announced that she would like to put a long brush down my throat to scrape it out.

At college the girls soon pointed out to me that I was a spoiled child and that I had no poise. They also called me a sissy because I had so little endurance when we went mountain-climbing, or even just hiking. But nothing much was said about my cough, for which I was duly grateful, and before the 4 years were over I could go to chapel and classes and be fairly relaxed. I did little in the way of extracurricular activities, and studied only enough to keep a B average, for my health was my first care. I took no medicine, but I was scarcely ever sick. The only time I went to the infirmary, I did so voluntarily to get a rest. There was another girl in the dormitory with a cold. During the night every time I coughed the nurse came in and gave her some medicine. In the morning she resentfully told the doctor about it. They decided to keep me until the cough was better. I had to tell my story, and they scratched their heads but let me go. Then there was a puzzled gym teacher who stood beside me during a vital-capacity test, insisting, 'But you certainly can do better!' until she gave up in disgust. But on the whole college wasn't so bad.

"After graduation I went immediately to a state hospital as a psychometrist. I was 20 years old but was still lacking in poise, and this was especially apparent in my contacts with men, which began at this time. One told me I had an inferiority complex. Someone from the hospital told my family that when I first arrived it had been thought I must be homesick because I seemed so depressed. These remarks did not trouble me, but made me begin to notice my reactions and moods. The hospital staff took a personal interest in my difficulties, and 2 years later offered to do some sinus operations, which helped me a good deal. After doing mental testing for 4 years I went to the Mid West and studied social work. One day I noticed that it was hard to breathe, and that it was fatiguing to move about. This feeling came in spells and was frightening

however, obviated this difficulty. On April 15, eighteen days after operation, the plaster cast was removed. X-ray examination of the chest in the lateral position showed that the sternum descended in a vertical direction. The posterior border of the sternum was 8.4 cm from the anterior border of the thoracic spine, as compared with 3.5 cm in the preoperative film.

This patient was discharged from the hospital May 24, two months after operation. His breathing was no longer restricted, cardiac action was free and digestion was normal. Nevertheless, we realized that it was too early to determine the ultimate result. Subsequent events indicated the importance of a conservative point of view in evaluating the results of this operation.

A search of the literature on funnel chest revealed very few operative cases. When only two or three costal cartilages were severed, symptoms ceased for a short time only and the end results were not satisfactory. Sauerbruch³ was the first to do extensive resection for this deformity. His first case was reported in 1913. He operated upon a second patient in 1931, but symptoms recurred.

Operative results in 9 congenital cases in children treated surgically were presented at the French Congress of Surgeons, 1934. These cases represented the surgical experience with funnel chest in Europe. The standard procedure was that of Garnier, a T-shaped sternotomy and ample resection of costal cartilages, as required.

In this country, Alexander⁴ of Michigan, in 1931 reported 2 traumatic cases treated by operation. The first patient was a boy sixteen years old, injured four years previously while wrestling. Even after bilateral resection of five costal cartilages the sternum could not be elevated. It was necessary to divide the sternum longitudinally before this structure could be raised. A special apparatus was employed for fixation. A tendency to recurrence disappeared after the patient had been given a course with blow board and an apparatus connected with the hospital traction system.

Alexander's second patient was a woman twenty years old who had been injured two years before in an automobile accident. The body of the sternum was removed from the third to the sixth rib, with resection of the attached costal cartilages. Symptoms were relieved and did not recur.

Carr⁵ reported a case in a young man nineteen years old who was operated upon. Head. He removed the left third, fourth, fifth and seventh costal cartilages, and the right fourth, fifth, sixth and seventh, and resected the lower half of the sternum and the xiphoid process. Carr refers to a second case which ended fatally, gives no

details. When a third case came to his attention, Carr stated that he was reluctant to subject another patient to surgery because of the great risk involved.

Our third case of funnel chest was seen January 6, 1937. The patient, a man thirty-one years old, had a depressed sternum dating from early childhood, but the deformity had given him no discomfort until two years previously. He then complained of sharp pain in the region of the left nipple, occurring about once a week. Epigastric distress, nausea and vomiting occurred at short in-

Figure 2.

tervals. Symptoms were more severe after the ingestion of fatty foods and after heavy meals. There was no dyspnea, no palpitation or cough and no noticeable loss of weight, but the man was unable to work.

X-ray examination of the chest two weeks before entry showed that the posterior surface of the lower end of the sternum was 1 cm from the anterior surface of the thoracic spine. The heart was entirely to the left of the midline. A lateral view of the spinal column showed marked scoliosis of the thoracic spine, convex toward the left. The electrocardiographic tracing showed some myocardial damage and sinus tachycardia.

From our experience and that of Alexander, Head, and the French surgeons, we concluded that the only operation which offered hope of perma-

A NEW METHOD OF DEALING WITH FUNNEL CHEST

PHILEMON E. TRUESDALE, MD

FALL RIVER

THE developmental anomaly of funnel chest was first reported by Bauhinus in the sixteenth century, but few cases had appeared in the literature up to 1900. This deformity is fairly common among children admitted to hospital clinics. Treatment, when required, is medical. In adults, however, funnel chest may greatly incapacitate the individual, so that some form of mechanical readjustment of the sternum is necessary in order to obtain permanent relief. Surgical needs for this complaint have been recognized in Paris by Ombrédanne and Garnier,¹ who adopted an operation that was fairly well standardized by 1935. It consisted of a T-shaped sternotomy with resection of the costal cartilages as required, followed by immobilization with a special orthopedic apparatus.

The cause of funnel chest is unknown. Many writers refer to its origin as congenital, while others believe that the condition may be acquired through trauma. Only a few traumatic cases, however, have been reported, because accidents which result in collapse of the sternum usually end fatally.

Our interest in this subject began in April, 1935, when we discovered that a funnel chest was a contributory cause of death following an operation for diaphragmatic hernia in a patient nine years of age. The marked degree of dextrocardia which existed was attributed to a shifting of the mediastinum due to the presence of the herniated hollow viscera. Much to our surprise, however, we found that with repair of the diaphragm and the return of a negative pressure in the left pleural cavity, the heart did not change its position from the extreme right. The patient died on the fourth day after operation. Postmortem examination revealed a permanent midline partition made by the sternum, and the physical impossibility of the heart's shifting to a normal position. The right ventricle showed hypertrophy, which was undoubtedly caused by pulmonary resistance.

Our next patient with this deformity was admitted to the hospital March 11, 1936 (Fig 1). He was eighteen years old, under weight, and appeared sick. For several years he had had dyspnea and "stomach trouble" associated with anorexia, nausea and dysphagia. Three months before admission the symptoms had become so severe that he was forced to give up his work as a clerk. His

weight had dropped from 170 to 140 lb in the last year.

Operation was done March 28 under avertin-ether anesthesia. The procedure has been described in an article² published in 1936. Briefly it consisted of disengaging the body of the sternum by severing the costal cartilages on both sides and dividing the

Figure 1

sternum horizontally at the level of the third intercostal space. Two perforations were then made through the lower third of the sternum about 2 cm apart, and through them a heavy silver wire was passed so as to form a loop for extension. The wire was attached to a windlass suspended from the crossbar of a wooden frame incorporated in a plaster cast fitted to the chest.

With this apparatus we were unable to obtain the desired degree of elevation of the sternum, because tightening the windlass produced a suction which closed the esophagus. Moderate elevation

operation. It seemed imperative, therefore, to evolve a technic which would relieve symptoms permanently, minimize the chances of infection and thus offer a reasonable hope of safety and cure. The method necessary to accomplish this result would entail removal of the sternum and the attached costal cartilages without opening the mediastinum. Since the cause of hemorrhage in the previous case was a suppurative mediastinitis, it was a matter of great importance not to have a repetition of this serious complication. It was therefore decided to attempt a complete subperiosteal excision of the depressed portion of the sternum and costal cartilages. Figure 3a shows the vertical incision over the sternum, and Figure 3b the amount of bony and cartilaginous portions of the thoracic cage which were resected. These structures were carefully severed without entering the mediastinum or pleural cavities. The periosteum and perichondrium were reflected from the body of the sternum and the costal cartilages respectively, and dissected free.

Figure 4 shows the steps in this procedure. (1) The depressed sternum with the attached costal cartilages is seen in situ. (2) The left costal cartilages have been stripped from the perichondrium. The heavy lines indicate the points of resection on sternum, xiphoid and right costal cartilages. (3) The body of the sternum from the third interspace to the xiphoid process and the attached costal cartilages on the right have been disengaged and elevated. (4) The bony and cartilaginous portions of the thoracic cage have been removed, leaving the periosteum and the perichondrium intact.

The dissection was accomplished without hemorrhage from any large vessel. On its completion there was no communication with the mediastinal space, the periosteum and perichondrium forming an improvised roofing for structures in the mediastinum.

The wound healed by first intention, and the patient made a comparatively comfortable recovery. He left the hospital symptom-free and has remained well since that time.

It is fair to assume that this patient is cured. Thus, from our experience with funnel chest, which has been fraught with disappointment and disaster, we have evolved a simple technic for dealing with a disabling deformity. This technic converts an extremely hazardous procedure into an operation which is relatively simple, rational, safe, and when supplemented by exercises, in all probability, curative.

DISCUSSION

DR. JAMES W. SEVER, Boston. I was very much interested in part of this paper when it appeared last year in the *New England Journal of Medicine*. I have looked up the literature because last year's report recalled a time many years ago when I was a house officer at Dr. Bradford's at the Children's Hospital. I begged him at that time to let me operate on some of the very badly deformed funnel chests that we saw in the Scoliosis Clinic, with the purpose of devising some means of lifting the sternum. At that time I had no idea of what had been done. As a matter of fact, very little had been done. Dr. Bradford was not willing, as he put it, to sacrifice any child to my enthusiasm. So my efforts stopped there.

There has recently been pronounced interest in this matter, and this work of Dr. Truesdale is at least hopeful, although some of it is discouraging. Apparently if anything is done, the best thing is to resect the lower portion of the sternum—not the manubrium.

We see at the Children's Hospital a great many cases of funnel chest. Most of them are mild. The very bad ones have never been improved by any postural treatment that I know of, and surgery is the only hope. If nothing is done, the result is always a high degree of structural scoliosis, tremendous heart displacement and embarrassment of respiration. So far as I can discover from the literature, some of the deaths that occur shortly after this operation are caused by the sudden twisting of the supporting structures of the heart, which have been displaced for a long period of time.

I wish Dr. Truesdale would say something about the question of opening the pleura, which varies greatly in its attachment to the posterior portion of the gladiolus.

We have had no traumatic cases of depression of the sternum so far as I know, and nothing particular is said in Dr. Truesdale's paper about the cause of severely depressed sternums. The only such case I have ever seen, which perhaps some of you may remember, occurred at a Harvard and Princeton football game many years ago. Holden, the captain of the Harvard team, tackled a Princeton man, whose knee hit Holden on the chest. Holden was carried off the field and taken to the Massachusetts General Hospital. He had a bad fracture of the sternum and nobody knew what to do. In a sudden reflex coughing spell he coughed the sternum back into place. Perhaps that is a satisfactory method of treatment.

DR. FREDERIC J. COTTON, Boston. I have been interested in the few cases of funnel chest that I have seen. I remember the Holden case. I was a house officer at the Massachusetts General when he was brought in. His gladiolus was driven in under the manubrium. I did not wait for an accidental cough, but stretched him over the end of the bed, grabbed his arms and had him cough, and the gladiolus went back into place. The report of that case was my first contribution to surgical literature.

Again, my interest in this condition was sharply aroused because my infant daughter had a pronounced funnel chest. One of her uncles also had a funnel chest, which was rather marked but it never incapacitated him. In my child's case the outlook was not very promising. Respiratory exercises, however, effected an absolute cure.

The third case I have in mind is that of an old nurse who came to me last spring on account of her back

nent relief of symptoms was a removal of the sternum. Therefore on January 16, ten days after the patient's admission, we did a subtotal excision of this structure. The thorax was opened by a lapel

Figure 3a

Figure 3b

incision. The sternum, together with the cartilaginous portions of the third, fourth, fifth, sixth and seventh ribs, was removed (Fig 2). During this procedure a minute opening was made in the

pleura on the right side, this resulted in a pneumothorax. On the third postoperative day x ray examination showed collapse of the right lung and a small amount of fluid at the base. The wound drained a moderate amount of seropurulent fluid. On the twelfth day death resulted from a sudden massive hemorrhage from the wound. Postmortem examination revealed an inflammatory process in the mediastinum with a thin seropurulent exudate. There was also an acute suppurative pericarditis. The source of the hemorrhage was an opening in the superior vena cava.

Two months after this experience the young man who had been operated upon March 28, 1936, returned to the hospital stating that the sternum had again become depressed to the degree present before operation. His symptoms had recurred, and he was again unable to work. He stated that he had received such marked relief after operation that he wanted to submit to another if considered advisable.

The outcome in our third case had been most discouraging. No standard technique had thus far been devised for removal of the sternum, and each case reported had presented many obstacles at

Figure 4

RIGHTS AND LEFTS IN MEDICAL PRACTICE

ROGER I LEE, M.D

BOSTON

PRESIDENT ELIOT was always fond of describing the advances in medicine as prodigious. And while there has been a great lag between the advances in medical science and their application to medical practice, nevertheless these marked advances have, of necessity, resulted in many changes in practice. For centuries, the medical practitioner, despite the buffetings of his social and economic status and despite, too, his variegated relation to scholarship, was a rugged individualist. Clearly Hippocrates conceived him as such and he so emerged at the beginning of the era initiated by the discovery of anesthesia and asepsis.

Your medical practitioner of that day had a purely personal relation with his patient. The hospital was essentially only an asylum for the sick poor. Preventive medicine was unknown. The apprentice method of medical instruction was the common and best method of instruction. Medical schools were largely private ventures. In the Harvard Medical School, for example, the attendance at lectures for two years, attested by punched tickets, sufficed for a degree. The lectures were ordinarily the same lectures repeated yearly. The state, that is, any governmental unit, took little or no interest. As the state began to interest itself in medical practice and established a system of licensure, applicants received a license either by passing an examination or by virtue of years of practice.

A second early step in the communities along the Atlantic seaboard was the evolution of the insane asylum under wretched county control into the mental hospitals under state control. With the consent of most of the interested bodies, the Commonwealth of Massachusetts, for example, began to care for the mentally ill. To be sure, a large factor in this step was the humane and successful treatment of mental invalids at the McLean Hospital, then as now a department of the Massachusetts General Hospital.

Another step was the introduction of the free distribution of vaccine virus in Massachusetts, followed by that of diphtheria antitoxin. The changing argument was interesting. It was successfully argued that if the State adopted compulsory vaccination in the schools, it should furnish the vaccine free. In the case of diphtheria antitoxin, following a tragic attempt in another state to corner for financial gain the available supply of diphtheria

antitoxin, the argument was the right and indeed the obligation of the State to protect its citizens from a communicable disease both by treatment and by prevention.

This argument has been pushed to cover all diseases dangerous to the public health, that is, essentially, the communicable diseases. But it is to be noted that mental disease, already a charge of the State, does not come under that category. And soon we find attempts to bring other diseases, usually chronic, under state control, such as cancer, arthritis, and the like. During this time, changes were being rapidly made in other directions, some involving directly or indirectly medical practice. Communities undertook public water systems and public sewerage systems. To be sure, there are still a few private water systems in Massachusetts as well as elsewhere, but they are very few. Many communities, or combinations of communities, undertook public lighting and power systems. Indeed, at this very moment, there is a titanic struggle between the forces of privately owned and publicly owned so-called public utilities. There we see more clearly the opposing fundamental lines of thought. The advocates and opponents of public ownership of such public utilities as light, power, telephone and railroads find, relatively speaking, a line of cleavage. And yet the mails are government owned and operated, and in England the radio, so far as broadcasting is concerned, is a governmental business.

Without going farther into details, one may pass to the subject of education. It has been accepted that education is an obligation upon the government and we see the natural and inevitable effect of pushing this to the so-called logical conclusion.

Great state universities have sprung up all over this country and with them have come state university medical schools, research departments and hospitals. Such has been the impetus that President Conant was moved to discuss whether the privately endowed university had a place in the modern trend of educational affairs.

There is neither need nor time to discuss the changing trend of the hospital—its change from an asylum for sick poor to an elaborate institution for the treatment of the sick both rich and poor.

In this prodigious progress, the medical practitioner is bewildered. He no longer finds himself a rugged individualist with the old intimate relation of doctor and patient. He finds the much despised boards of health of yesteryear aggressively

symptoms. She had a funnel chest, but it was not extreme. The back symptoms did not amount to much and cleared up, but she still was quite anemic. I suspected that the lack of respiratory capacity had a good deal to do with it, so I started her on exercises. She carried them through, spent a summer out-of-doors, and turned up in my office the other day with a practically normal chest. She lifted the sternum out by exercises, and I think a good deal can be done in that way.

DR. GEORGE M. SABIN, Burlington, Vermont. I should like to ask Dr. Truesdale about the hemorrhage in these cases—the successful cases.

DR. TRUESDALE. There was practically no hemorrhage. By keeping inside the periosteum and perichondrium one escapes the danger of traumatizing the pleura and of cutting the internal mammary artery.

DR. FRANK R. OBER, Boston. There are not so many funnel chests as there were when rickets was a common disease. This condition is known as cobbler's disease. A cobbler frequently developed a funnel chest from his position in repairing shoes and cleaning boots, and yet might live to a ripe old age. The congenital type is relatively common. If you become enthusiastic over this operation of Dr. Truesdale do not do it to the exclusion of all other treatment for funnel chest. At the Children's Hospital we put these patients on hyperextended frames and give them deep-breathing exercises. They respond to such treatment very well. One should employ this method for at least five years and should not wait until the child has arrived at the age when his bones are fixed and solid.

DR. ELLIOTT C. CUTLER, Boston. Considering the physiology of respiration, it appears that removal of the sternum would seriously jeopardize the ability of the lungs to fill adequately. I have observed that following the operation of pericardiectomy, where a part of the sternum and the adjacent ribs on the left side are removed for proper exposure, respiratory efforts reveal a considerable sucking in of the soft parts of the anterior chest wall, with a resultant lowering of the vital capacity. I wish Dr. Truesdale would tell us whether he has made studies of the vital capacity of the boy who survived the procedure he has described.

It seems as though the inspiratory effort would cave in the unsupported soft parts and thereby interfere somewhat with respiration. All those interested in thoracic surgery would, I am sure, welcome information on this point.

My other question relates to the possibility of recurrence of the condition. If this is a congenital anomaly, it may be caused by something which increases respiratory effort, such as a tracheal stenosis or a mild bronchial obstruction. If the condition persists, I should suspect that as the periosteum reformed bone it would still be sucked in by the mechanical difficulty of the primary anomaly, and thus the funnel chest would recur.

What has been said by both Dr. Cotton and Dr. Ober about breathing exercises may well have had a part in the ultimate cure of this boy.

DR. TRUESDALE. I am unable to answer the questions bearing upon the patient's vital capacity before and after removal of the sternum. After operation this young man said that he felt as though a very tight belt encircling his chest had been removed, and that he could climb stairs and do many things that he had been unable to do before. It is possible that when there is some bone formation he may again have a retraction of the chest wall. In the meantime, however, he has been prescribed systematic simple exercises and deep breathing. In this way we hope to keep the region of the sternum on a level with the anterior wall of the thorax.

Dr. Cotton and Dr. Sever mentioned snapping out the sternum after it has been depressed by a sudden injury. If these cases are caused by trauma and if they come to the hospital early enough, you can see from what has been said that the deformity can be corrected readily and without difficulty. It is probably true that the funnel chests which we have seen in adults had their origin in childhood from congenital causes such as rachitis. The funnel chest is slight at first, and the depression seldom becomes so marked that the patient cannot work. When it does, as in the cases reported in this paper, surgical intervention is indicated. The cases with spinal curvatures and the congenital types often develop tuberculosis. Inter-current tuberculosis of the lungs has been reported as a complication in some of the advanced cases, as mentioned by Dr. Sever.

itics makes strange bedfellows, for example the union of the prohibitionists and the bootleggers

But, shall we say that the Rights are those who believe that the advances in medical practice which result in governmental control by the use of public funds are proceeding at too fast a pace? Certainly, as I see it, the pace is terrific. All along the lines there seems to me to be too great wastage. But three most important considerations stand out in my mind. I believe that medical tradition has value. I believe that medicine has just barely become a science, and dread the effect of projecting this new science entirely into the seething furnace of politics. Will the prodigious advances continue then? Lastly, I believe that in many instances of seeming emergency, in which govern-

mental aid is involved, an ardent individual enterprise, determination and aggressiveness will frequently accomplish something that pessimistic inactivity never will. And this applies to private hospitals and privately endowed medical schools.

As you gather, I am decidedly on the Right in this question. Perhaps it is because I am a Fellow of Harvard College, a privately endowed body, or because I am a Trustee of the American Medical Association, or because I served for a number of years on the Massachusetts State Board of Health, or am on the Advisory Committee of the United States Public Health Service. But, consistency is a certain virtue of small minds.

264 Beacon Street.

THE TREATMENT OF THE VOMITING OF EARLY PREGNANCY

DUNCAN E. REID, M.D.,* AND HAROLD M. TEEL, M.D.†

BOSTON

NAUSEA and occasional vomiting of two or three weeks' duration are so common in early pregnancy as to appear almost physiologic in origin. They occur to some degree in approximately half of all pregnancies. Their frequency and duration vary greatly in individuals, as well as in different pregnancies in the same individual. But if the vomiting is of such frequency and persistence that it materially interferes with fluid balance, acid-base equilibrium or other phases of nutrition, it is potentially dangerous and must be regarded as abnormal. When the disturbance is as severe as this, it is commonly referred to as hyperemesis gravidarum, or pernicious vomiting.

The incidence of such abnormal vomiting at the Boston Lying-in Hospital is approximately 1 for each 150 deliveries. More than half these cases, however, have been referred by private physicians or other hospitals for treatment, so that the true incidence is nearer 1 in 400 deliveries. Our remarks will be confined largely to the treatment of the excessive or abnormal vomiting of pregnancy as defined above.

ETIOLOGY

The cause of the disease is unknown. In the recent literature two important trends of thought have been expressed. First, it has been contended that response to a specific form of therapy points to a specific etiologic agent.^{1, 2} Needless to say, most

of the glands of internal secretion, and particularly those intimately associated with reproduction, have been thought to perform their functions either inadequately or too well. As might be expected, many forms of endocrine therapy have been used, and have for the most part been credited with good results. It is fair to state, nevertheless, that these preparations are usually employed in conjunction with other therapeutic measures. Also, many forms of treatment without endocrine preparations are attended with reasonable success except in an occasional patient. Indeed, in the vast majority of cases successful therapy in hyperemesis gravidarum is, it seems, more nearly correlated with the degree of conviction under which it is prescribed than with the specific therapeutic measures involved. Secondly, there has been a trend to the study of the secondary nutritional and metabolic alterations which result from vomiting.^{3, 4, 5} These disturbances are the results of loss of body fluid and sodium chloride, associated with varying degrees of carbohydrate, protein, mineral and vitamin deficiencies. The pathological findings in fatal cases demonstrate the importance of many of these resultant nutritional disturbances. The common lesions at autopsy may be reproduced in starvation experiments.

During the past four years at the Boston Lying-in Hospital, the treatment of vomiting of pregnancy has been directed primarily at the correction of each of these nutritional disturbances which accompany and often aggravate the disease.

It is our belief that indiscriminate use of the term "neurotic vomiting" has been productive of

Read at the combined clinical meeting at the annual meeting of the Massachusetts Medical Society, Boston, June 2, 1937.

interested in his cases of measles, pneumonia, cancer and arthritis. He finds the hospitals in active financial competition with him. Sometimes, when his altruism impels him to send his patient to a hospital, irrespective of whether or not he takes care of the patient there, the hospital charges, when paid, preclude recompense for the doctor. Not infrequently the patient has a parent or relative, or perhaps a friend, who pays for the hospital room, and another who pays for special nurses, but the doctor must be paid, if at all, by the patient who neglected to budget for illness.

He sees the veterans' hospitals increasing in size and numbers, and he sees each Congress relaxing the restrictions on the use of these hospitals. He is most definitely unhappy about the operation of accident insurance and of the various industrial boards. To increase his confusion all sorts of panaceas are offered him—general health insurance in many forms, co-operatives, group medicine, and the like. To him it seems as if the old traditions of medicine, the rugged individualism of the doctor, and the opportunity of earnest, strenuous effort on the part of any single physician were all cast overboard. He is oppressed by the mass-production note on all sides.

As he thinks, he gropes for some solution. To some of the doctors, the idea of the totalitarian state no longer seems absolutely theoretical and crazy. Does not each year find an increasing number of doctors employed by the town, the county, the state and the federal government? Certainly, there is no indignity attached to a position on the local board of health or to a paid position in the local hospital, in one of the state hospitals, in the State Department of Public Health, in the United States Public Health Service or in one of the government hospitals in the Veterans' Bureau. Certainly many notable figures in medicine are employed in the great state medical schools and hospitals. He knows really that economic pressure is a very vital factor that often furnishes the motive power for changes. And, so, ordinarily, the fundamental and philosophic conception is largely disregarded even as it was largely disregarded by those instrumental in bringing about these changes. The word security, social or financial, has a great psychologic effect.

Inasmuch as this is a selfish world and most motives are selfish, your medical practitioner acts selfishly, like anybody else. If his practice is mostly among the poor, he may like to consider how some governmental unit will pay for his professional visits to the sick poor. Naturally, he wants as little governmental control or interference as possible. (Is this very different from the old reiterated expression of the big business men?)

Some practitioners of medicine, however, would go the whole distance—the complete totalitarian state—so far as medicine is concerned. These, I think, we can safely call the Lefts. But what of the practitioners who only want pay from some public purse for each of their professional services? And what of the practitioners who only want open hospitals, whether private, community, state or federal, and payment for each separate professional service?

Of course, there are always troublesome details. Many communities are now in economic distress because of their relief programs which may or may not include expenditures for medical services. And what of this new term "medically indigent" and how far can public funds be extended to pay for professional services for those who use their in come for clothes, automobiles, radios and liquor? And what of hospitals, hospital salaries, medical schools and medical research? Shall we give up our privately endowed universities and hospitals? How irksome would be the supervision of the expenditure of public funds under these conditions? Probably only the out-and-out believers in the totalitarian state would want all medicine controlled by some governmental unit.

Doubtless, the great state universities have had a very beneficial effect on those privately endowed, and by the same token the privately endowed universities have had and will continue to have, I believe, a beneficial effect on those of the state. Personally, I cannot accept the pessimistic utterances of President Angell of Yale at the Harvard Tercentenary in 1936 when he solemnly declared that the trend of greatly increased taxation incident on these and other changes would probably close the privately endowed universities.

We can easily define the Lefts in medical practice as those who have been led to believe as they do either through conviction or from what they think is pressure to avoid destruction. But what of the Rights? Who are they? The exigencies of the situation do not permit the existence of the rugged individualism of practice of the earlier days. And most thinking persons accept and endorse much of the activity in medical practice by various governmental units. Some, indeed perhaps many, of these look askance at such activities as veterans' hospitals with the gradual loosening of the earlier restrictions.

A considerable group, no one knows how large, feels that while each step may be superficially justifiable, nevertheless, the trend taken with similar trends in other fields is now overdone. Are health and education different from crops, clothing and other necessities of life? Should one believe in governmental control of products and not of health? Of course, logic is impossible, and pol-

- 3 The ever present constipation is corrected by the use of enemas until the lower bowel is empty, and insistence upon either one bowel movement daily thereafter or repetition of the enema.
- 4 Fluid and sodium-chloride balance are restored, and acidosis is corrected.
 - a. An initial hypodermoclysis of 1500 cc of normal saline is given, followed by sufficient amounts daily to achieve and maintain fluid balance until the patient is retaining food and fluid by mouth
 - b. An intravenous infusion of 5 or 10 per cent glucose solution is administered by constant drip at a rate of from 30 to 40 drops per minute in sufficient amount to keep the urine relatively free from ketone bodies. This should be repeated at intervals of from 8 to 12 hours until the patient is retaining sufficient carbohydrates by mouth. If given slowly by constant drip, from 1000 to 1500 cc. or even more is well tolerated every 24 hours. After the fluid balance has been restored, the total fluid intake in glucose solution intravenously and saline by clysis should not exceed 3000 to 3500 cc. in 24 hours
- 5 Control of the starvation and resultant change. As vomiting persists, additional nutritional deficiencies in protein, minerals and vitamins come to play increasingly important roles in the pathology of the disease. With this in mind in each case, the duration and severity of the vomiting are considered, the dietary history is surveyed, and signs of vitamin deficiencies are sought. A well-balanced diet is provided with such supplementary vitamin concentrates as seem advisable. If the patient has reacted well to 12 or 24 hours rest, with parenteral fluids and sedatives, such a diet in small amounts and in the form of liquids is offered at hourly intervals by mouth. If there is still nausea, or if food taken by mouth is vomited, a generous dose of sedative is given by rectum, and one hour later a duodenal tube is passed through the nose. When this has been done, feedings of liquid diet are given at hourly intervals by drip at body temperature. We often begin with orange juice sweetened with corn syrup, milk, and eggnog (4 oz.) in succession at hourly intervals. A heaping teaspoonful of brewer's yeast concentrate is added to each milk feeding. If dietary history and study of the patient so indicate, larger amounts of vitamin B₁, ascorbic acid and liver extract administered intramuscularly are given. There is, occasionally, regurgitation of part of the feedings during the first 24 hours. This should not cause great concern, nor is it of much importance whether or not the tube has entered the duodenum, for excellent results are usually obtained when it rests in the stomach. The tube is left in place for 12 hours, and moderate doses of sedatives are administered through it at approximately 6-hour intervals. This method of feeding is continued for from 3 days to a week or more with gradually diminishing amounts of sedatives, following which the patient is given a well balanced diet of high vitamin content by mouth. When vomiting has ceased for 1 week and the pulse rate is well below 100, the patient is allowed to be up and about. On discharge, she is instructed concerning a well-balanced diet, rest, and proper control of the bowels. Brewer's yeast, small doses of sedatives and iron are continued for a considerable time.

Response to this treatment may be briefly exemplified by the following case history

Case 1 D A, a primipara, aged 23, entered the hospital in the 6th week of pregnancy. Vomiting had begun 11 days before admission, only small amounts of fluid had been retained. There was a history of a 10 lb loss in weight and marked constipation. The essential positive findings were signs of dehydration, a pulse rate of 88 to 110 and 3+ acetone and 2+ diacetic acid tests in the urine. The patient was treated as outlined. The acidosis was promptly controlled, and vomiting ceased during the first 24 hours after admission.

This patient's moderately severe vomiting responded ideally to the treatment. Although a large majority of such cases respond promptly to the treatment described, there is an occasional exception, and we believe that therapeutic abortion has its place in the proper treatment of this disease.

Should the patient continue to vomit in spite of a fair trial of four or more days of treatment as outlined, abortion should be considered. This is particularly true if the patient's pulse increases to a sustained rate of 110 or 120 beats per minute, if bile appears in the urine or clinical jaundice develops or finally if any one of the neurologic signs previously discussed appears. Such a course may be illustrated by the following clinical history.

Case 2 M. S. was a primipara of 28 in the 12th week of pregnancy who entered the hospital for severe vomiting of 4 weeks duration. The positive findings were incessant emesis with vomitus untinged with blood, tingling of hands and feet for 1 week, a pulse rate of 80 to 110 and marked dehydration and ketonuria. The patient failed to respond to treatment, and incessant vomiting continued in spite of attempted tube feedings. She was then given large doses, first of estrin and later of suprarenal cortex extract, but with no improvement. Finally, catheters were inserted into both ureters as suggested by Hayes.⁶ The patient failed to improve in spite of all treatment. The pulse rate continued to increase steadily and rose to 160. Therapeutic abortion was performed vaginally on the 7th day after admission. On the 2nd and 3rd postoperative days the patient developed a mild psychotic state, which was transient. She was discharged 8 days later with a pulse rate of 90 and no complaints.

It should be emphasized that the condition of this patient was rapidly becoming desperate, and that all methods of medical treatment, including endocrine therapy, were failing. In retrospect, it seems that it would have been better to resort to therapeutic abortion forty-eight to seventy-two hours earlier.

Severe or neglected cases are characterized by continuous vomiting, usually of more than four weeks' duration, with marked to extreme loss in weight, dehydration and acidosis. The pulse is accelerated, and the rate is usually above 120. Jaundice may be present. Bleeding, spongy gums are a frequent finding, other signs suggestive of scurvy, such as hematuria and muscle and periosteal pain, may be encountered. Hemorrhages of the ocular fundi are occasionally found. The neurologic signs and symptoms may be well established. Men-

some confusion and harm. To be sure, psychic disturbances are among the most important of a large group of extrinsic factors which aggravate the disease. However, there can be no doubt that many physicians have been prone to dismiss vomiting of pregnancy as a neurotic disturbance, without adequate treatment. We must emphasize that each patient with hyperemesis, if treatment is neglected, has a potentially dangerous or even fatal disease.

LABORATORY FINDINGS

Most important of the laboratory procedures is examination of the urine. Except in mild cases it should be examined twice a day until the disease is under control. The volume and specific gravity should be determined, tests should be made for acetone, diacetic acid, albumin, sugar and bile, and the sediment should be examined.

Blood samples taken for study when the patient is markedly dehydrated must be interpreted with this fact in mind. Abnormally high hemoglobin values and red-blood-cell counts may be due to blood concentration. Similarly, the nitrogenous constituents of the blood are many times found to be elevated. The latter usually return to normal values promptly when fluid and sodium-chloride balances have been restored, while re-examination for hemoglobin and the red blood cells often reveals a relatively severe microcytic, hypochromic anemia which had been masked by blood concentration. Marked decrease in the carbon-dioxide combining power of the blood in many instances precedes a fatal outcome, yet, death may occur in patients with normal or even elevated values.

CLASSIFICATION

There are two interrelated variables in this disease—the *severity* and the *duration* of the vomiting. In order to formulate the best treatment for each individual case, both variables must be considered. Consequently, the cases have been classified as follows:

Vomiting of early pregnancy

Mild (morning sickness), no significant interference with nutrition

Moderately severe, duration from 1 to 4 weeks

Severe and neglected, duration over 4 weeks

Vomiting of late pregnancy. We do not believe that this is the same disease as that occurring early. It is often associated with severe pre-eclampsia, intestinal obstruction, abdominal inflammatory disease or lesions of the liver.

TREATMENT

Vomiting of Early Pregnancy

The treatment of the vomiting of early pregnancy may be either medical or surgical. We feel that both forms possess definite limitations. In general, the management may be outlined as follows:

Mild cases are characterized by considerable nausea and only occasional vomiting. In many instances there is only morning sickness, while in others the nausea and vomiting occur in the afternoon, or only with excitement or fatigue. The majority of patients never get beyond this stage, and there is no significant disturbance of nutrition. The treatment is medical, the most important measures being:

1. Frequent small feedings of any type of food which appeals to the patient. A high-carbohydrate, well-balanced diet is encouraged, and fatty, fried or indigestible foods are eliminated.
2. Avoidance or correction of constipation, with use of mild cathartics and enemas when necessary.
3. Removal of environmental factors which might aggravate the condition.
4. Rest, avoidance of excitement and fatigue, and sedatives when indicated.

Moderately severe cases are characterized by marked persistent nausea and vomiting with retention of very little or no food or fluid of from one to four weeks' duration. These patients show a loss in weight, dehydration, ketonuria and a beginning increase in pulse rate, and occasionally a small amount of bile in the urine. Nearly all are markedly constipated, and many show slight temperature elevation, which rarely exceeds 100°F. Occasionally there are one or more signs of beginning mental and neurologic lesions, such as defective memory, drowsiness, irrationality, nystagmus, decreased or absent tendon reflexes, atrophy and weakness of the muscles of the extremities,—particularly the extensors,—loss of sphincter control and sensory skin changes. We have included in this group only patients in whom the duration of the vomiting was four weeks or less, since clinically this appears to be a good dividing line between the moderately severe cases and those which are likely to be gravely ill. The management of such cases may be outlined as follows:

1. The patient must be hospitalized, and complete physical and neurologic examinations must be performed.
2. Treatment of the hyperirritable nervous system and the psyche is begun.
 - a. The patient is isolated from all friends and relatives as well as from oversolicitous attendants.
 - b. Measures are taken for the adjustment of mental problems which seem to be contributory factors, that is, illegitimacy, determination to be aborted or problems concerning husband and family.
 - c. Sedatives are given in sufficient quantity to cause cessation of vomiting and at first to induce sleep. Later, the doses are diminished. Phenobarbital, bromides and pentobarbital are preferred. It is usually preferable to give the medication by rectum following an enema. From 3 to 9 gr of pentobarbital are ordinarily required for proper control.

trial on this regime, therapeutic abortion was performed, in severe and desperate cases, it was usually done as soon as fluid balance had been restored by parenteral fluids

Table 1 *The Results from the Treatment of Moderately Severe and Severe Cases of Vomiting of Pregnancy at the Boston Lying-in Hospital*

	1930-1933	1934-1937
Number of deliveries	12 675	14 600
Number of vomiting cases	85	91
Incidence	0.63%	0.62%
Cases treated without therapeutic abortion	65	86
Deaths	4	0
Mortality	6%	0%
Cases treated with therapeutic abortion	13	3
Deaths	3	0
Mortality	23%	0%
Cases discharged against advice	7	2

Since 1933 the regime here outlined has been substituted. The results, in the moderately severe and severe cases, compared with the previous four-year period, are given in Table 1

CONCLUSIONS

- 1 The cause of the vomiting of early pregnancy is unknown
- 2 The pathologic lesions are those of starvation, resulting from sustained loss of body fluids, proteins, minerals, chlorides, carbohydrates and vitamins
- 3 An arbitrary classification on the basis of

the severity of the disease has been presented, and an attempt has been made to outline what appears to be the most satisfactory treatment for each group. A medical regime which has resulted in few failures has been suggested.

4 Therapeutic abortion is a life-saving procedure in early cases which fail to respond to a thorough trial of medical treatment. Clinical signs and symptoms indicative of such failure are emphasized.

5 In contrast to previous views on the use of therapeutic abortion in cases of neglected and long-established vomiting (severe type), we believe that immediate abortion is not indicated, but is best postponed for two weeks or more until medical treatment has restored the patient to a proper state of nutrition. If after this preliminary preparation therapeutic abortion is still to be considered, because of persistent polyneuritis, it may be much more safely performed.

LOW-THIGH AMPUTATION

Technic Employed in Elderly Patients, Particularly Those with Advanced Peripheral Vascular Disease or Diabetic Gangrene

G EDMUND HAGGART, M.D.,* AND GEORGE G. BAILEY, M.D.†

BOSTON

AMPUTATION of an extremity is performed for one of two purposes—to save life or to improve function. In older patients, particularly those who exhibit advanced peripheral vascular disease, or diabetic gangrene of the lower leg and foot, amputation frequently has to be considered, and the operation when carried out is done primarily to save life. Either because the change in the peripheral vessels is such that circulation cannot be sufficiently improved to save the part, or because diabetic gangrene, especially on account of a deficient circulation, makes it impossible to control the infection, the radical procedure of amputation is indicated.

*From the Bone and Joint Service of the Lahey Clinic.

†Head of Bone and Joint Service, Lahey Clinic.

†Formerly assistant orthopedic surgeon, Lahey Clinic.

The decision for or against amputation is often an extremely difficult one. Each patient presents a distinct problem. Consultation with the medical and the surgical services is always obtained, so that the patient has the benefit of three or more independent opinions.

The present paper is based upon a group of 38 elderly patients who, between January, 1932, and January, 1937, submitted to low-thigh amputation. The type of lesion for which they were operated upon is shown in Table 1. Exclusive of the fourth group (patients with thromboangitis obliterans), the youngest patient was fifty years old, the eldest was seventy-nine and the average age was sixty-two. In the fourth group the average age was forty-two. Incidentally, all the patients in this group

tal symptoms such as confusion, irrationality and hallucinations may appear. Nystagmus, diminished or absent tendon reflexes, marked wasting of the extremities, extensor paralysis, sphincter incontinence and sensory changes may be observed. The concentrated urine, in addition to ketone bodies, may show bile and albumin, as well as casts and blood in the sediment.

These patients present desperate problems. The mortality is probably well above 25 per cent, and past experience indicates that any surgical procedure adds materially to the risk. Immediate therapeutic abortion may well increase rather than decrease the mortality. Fortunately, in many patients who have progressed to this state the vomiting has diminished in intensity or has ceased, so that with the aid of the duodenal tube they may be fed. This is particularly true of patients who have developed polyneuritis.

With realization of the extremely high mortality which had attended immediate therapeutic abortion in this group, we decided four years ago to adopt a more conservative policy. A number of these cases have been treated in the manner described above for the moderately severe ones, with particular emphasis on prolonged tube feedings of a diet rich in protein, carbohydrate and vitamins, supplemented by concentrated sources of vitamins B₁, C and G in the form of brewer-yeast concentrate, ascorbic acid and liver extract given intramuscularly. Improvement has been marked and none of the patients have died, although in 2 with marked polyneuritis no significant neurologic improvement occurred until after the pregnancy had terminated. This point is well illustrated by the following case history.

Case 3. A. S. was a secundipara, aged 30, who was admitted in the 19th week of her pregnancy. Severe vomiting had resisted home therapy for 12 weeks, but 4 weeks before admission it had nearly ceased and an intractable diarrhea had begun. Since that time there had been complete paralysis of the lower extremities and marked weakness of the hands. The patient had lost 50 lb. in weight. The positive findings were anorexia, a sustained pulse rate at rest of 120 to 130, marked wasting of the muscles of the lower extremities, with absent deep-tendon reflexes and bilateral foot drop. The patient was slightly euphoric, and there was incontinence of both urine and feces. The urine showed a 4+ test for acetone. The blood showed moderate anemia, but the carbon-dioxide combining power was normal. This patient was treated as outlined. She was kept in the hospital for 4½ weeks. The diarrhea promptly subsided, the appetite improved, there was a gain in weight, and the pulse rate decreased slightly. The patient continued with complete bed rest at home, and in addition to a high vitamin diet took large doses of brewer-yeast concentrate until delivery 4 months later. In spite of these measures, the neurologic signs and symptoms did not improve significantly. Following delivery

neurologic improvement was dramatic, and 6 weeks post partum the patient was able to walk about the house.*

It is our feeling that in this type of case immediate therapeutic abortion is contraindicated. Ideally, we believe these patients should be fed a diet high in protein, carbohydrate and vitamins, with supplementary sources of vitamins, for at least two weeks before interruption of the pregnancy is considered.

The uterus should be emptied with the least possible trauma. If the cervix is firm, a small gauze pack should be inserted and left in for twenty-four hours. This results in a softening of the cervix, which will make subsequent dilatation and curettage easy. If the pregnancy has entered the second trimester, it is usually best terminated by vaginal hysterotomy. The added shock of abdominal hysterotomy appears to make this procedure undesirable.

The choice of anesthesia is important. Avertin should not be used. Morphine or the barbiturates may be used for preliminary medication. Inhalation anesthesia is to be avoided if possible, particularly chloroform and ether. Cyclopropane or ethylene is suitable. Sacral block with novocain or, on occasion, low-spinal anesthesia, is to be preferred.

Vomiting of Late Pregnancy

This is considered by many as a separate disease. Certainly it is often associated with pre-eclampsia, liver lesions or acute abdominal lesions. It is the feeling of obstetricians of long experience, however, that vomiting of late pregnancy from whatever cause is poorly tolerated. In the absence of demonstrable abdominal disease or pre-eclampsia, a short trial of medical treatment as previously outlined is permissible. However, if vomiting persists induction of labor should be considered.

RESULTS

Prior to 1934, patients with vomiting in early pregnancy were treated with a regime of which the essentials were isolation, no demonstration of sympathy, large amounts of parenteral saline and glucose (up to 6000 cc. in twenty-four hours), rectal taps with sedatives and feedings by mouth consisting of 8-ounce quantities of milk, malted milk and water in succession at hourly intervals. The strict hourly feeding schedule was maintained, and if significant vomiting recurred, all food was discontinued until vomiting had ceased for twenty-four hours, when feedings were resumed. If the vomiting could not be controlled after reasonable

Recent preparations of crystalline vitamin B₁ have been made available for parenteral clinical use. It may be that very large doses of this substance would have a more decided influence upon the polyneuritis which complicates prolonged vomiting than do preparations fed by mouth.

divided in the line of incision about 1 cm distal to the skin edges, as described by Kirl.

The mesial hamstring muscles and tendons are next divided, through blunt dissection in the popliteal space it is then easy to recognize, isolate, clamp and cut the popliteal vessels and nerves (Fig 2). With an amputation knife the remaining soft tissues are quickly severed. Comparatively slight bleeding results. The synovial membrane lining the suprapatella pouch is then cut away. Gentle

Figure 2 Following division of the medial hamstring muscles blunt dissection in the popliteal space permits easy recognition, clamping and cutting of the popliteal nerve and vessels. As described in the text, the saphenous vein is similarly clamped. With this technic a tourniquet is unnecessary. The insert shows the anatomy of the popliteal space, as seen at operation the hip flexed to 90° and the knee joint extended.

traction is applied to the sciatic nerve trunk, which is then divided with cautery, as suggested by McKuttrick. This technic is distinctly preferable to the use of ligatures and to nerve injection with absolute alcohol.

After exposure of the femoral shaft the periosteum is stripped from the bone toward the knee with a broad, sharp elevator, beginning 1 cm above the selected point of bone division—the aperiosteal type of amputation. Then the shaft of the femur is cut through, and the resulting sharp bone edge is beveled off with a rasp. The popliteal vessels are ligated twice with heavy silk.

Following low-thigh amputation, the femoral shaft tends to be displaced to the lateral side of the stump. For successful function of the prothesis it is most important to prevent such a displacement. This is simply accomplished by holding the femur in the mid-thigh position, and then passing anteroposterior silk ligatures through the muscles close to the bone on the medial and lateral aspects of the femur, this creates a muscular tunnel which incloses the shaft of the femur and prevents displacement to either side of the stump (Fig 3).

The anatomic relation of the soft parts to the

femur is now considered, and the key points for approximation of the skin edges are identified by clamps applied to the subcutaneous tissue. A careful survey is made for all bleeding points, which are clamped and cauterized. The larger superficial vessels, such as the saphenous veins, are tied with plain catgut. The quadriceps tendon is then sutured with chromic catgut to the posterior deep fascia at the midline so that the tendon lies directly over the bone end. This heavy tendon provides a most satisfactory coverage of the bone and permits weight-bearing on the end of the stump.

Figure 3 Prevention of lateral displacement of the femoral shaft by means of anteroposterior silk sutures deeply placed in the muscle mass on either side of the bone, thus creating a muscular tunnel which encloses and holds the femur in midline of the thigh.

Note that the distal centimeter of the femoral shaft is completely denuded of periosteum, also that the femur here is of a triangular shape since it was divided, as described in the text a few centimeters proximal to the cartilaginous margin on the anterior femoral surface. The next step in closure of the wound is suture of the quadriceps tendon to the midline posterior deep fascia, thus covering the end of the bone with this tendon.

Thereafter, the subcutaneous tissue and finally the skin are closed with interrupted sutures, the former with catgut and the latter with silk. Continuous sutures are not favored, as with their use an unnecessary amount of suture material remains in the wound.

Drains are not employed except in the presence of severe leg infection or in the rare instances of excessive oozing from the cut surfaces of the stump, sometimes seen in pronounced secondary anemia. In the majority of these amputations drainage is not necessary, in fact it is definitely contraindicated, as drains tend to create a sinus tract.

Following closure of the wound, a large, loose gauze dressing is applied and the entire stump is snugly covered with sheet wadding, followed by

had had prolonged medical treatment as well as lumbar ganglionectomy up to two years previous to amputation. It will be noted that patients suffering from arteriosclerotic gangrene form the largest single classification. In the entire series there was 1 death due to sudden rupture of an aneurysm of the abdominal aorta two months after amputation.

A discussion of the various levels of amputation is not indicated here, except to point out that

Table 1 *Reasons for Amputation.*

DIAGNOSIS	NUMBER OF PATIENTS	DEATHS DUE TO OPERATION
Arteriosclerotic gangrene	12	0
Diabetic gangrene and arteriosclerosis	9	1
Diabetic gangrene	6	0

amputation below the knee is rarely to be considered in older patients with diabetic gangrene of the lower leg and foot, unhealed lesions of the foot due to inadequate circulation, or a combination of these two conditions. Furthermore, after amputation through the lower extremity in older patients there is concern about future function, especially in the younger ones. The use of an artificial limb is always trying for older people. Nevertheless, with the most important aid of an expert maker of artificial limbs, we were successful in fitting 37 patients in this series with a prosthesis which functioned—a difficult but well worth-while task.

Having decided upon a thigh amputation for a case in this group, selection of the type of operation lies essentially between a Gritti-Stokes procedure and amputation through the lower thigh. For these patients, particularly in the presence of deficient circulation or diabetic gangrene, we believe that the latter procedure is preferable, for these reasons:

- 1 It is simpler and safer.
- 2 There is consistent primary union.
- 3 Weight can be borne on the end of the stump as a result of suturing the heavy quadriceps tendon over the femoral shaft to the posterior deep fascia (Kirk).
- 4 Osteogenesis (patella to femur) is not required.
- 5 The resulting stump affords excellent leverage for a prosthesis.

Low-thigh amputation as here reported means division of the distal femur through the expending bone shaft 3 to 5 cm. above the proximal cartilaginous margin on the anterior femoral surface.

Since this group of relatively old patients has reacted so favorably to the operation, we shall describe the details of the procedure, which is the method now employed in the Lahey Clinic.

A proximal tourniquet is not applied, since any degree of obstruction to circulation may delay healing and because with the technic described very little blood is lost. Every attempt is made to drain the leg of blood by elevating the extremity, beginning with the time the patient is placed on the operating table. In the *absence* of infection this step is supplemented by a progressively tight elastic bandage on the foot and lower leg as far up as the knee. This bandage squeezes nearly all the blood out of the lower half of the leg. In the *presence* of severe lower leg infection a tourniquet is applied very tightly just below the knee.

The operation is performed with the patient lying supine, while an assistant holds the extremity flexed at the hip to a right angle, the knee extended (Fig. 1). This position offers ready

Figure 1 Illustrating the position in which the leg is held for amputation. The advantages are facility of approach to the operative field as well as drainage of blood from the extremity. The insert shows line of incision.

access to the site of the incision and greatly facilitates the entire procedure.

The incision for the anterior skin flap passes through the mid-patellar region, while the posterior flap is outlined slightly proximal to this level (Fig. 1). The use of flaps is preferred to the guillotine type of incision because with them there is a neater-appearing stump and it is easier to cuff back the soft parts for exposure of the bone. After the saphenous vein has been clamped and cut, the deep fascia on the posterior aspect of the thigh is

INTRAVENOUS EVIPAL—SODIUM ANESTHESIA IN UROLOGIC SURGERY

JOHN E. DUNPHY, M.D.,* AND JOHN H. HARRISON, M.D.†

BOSTON

EVIPAL SODIUM was first used as an intravenous anesthetic at the Peter Bent Brigham Hospital in 1934. At that time it was felt that though the pharmacology of this new anesthetic had been inadequately studied,¹ the extensive experiences of German and British investigators justified its clinical trial. In a previous communication² our experience with 300 cases was reported. The importance of individualization in the use of evipal sodium was emphasized. Certain indications and contraindications were discussed and a technic of administration which had proved safe and practical was outlined.

In the present paper, particular attention is given to the applicability of evipal anesthesia to urologic practice. No branch of surgery more frequently requires an anesthetic for procedures of short duration than does urology. On the other hand, no branch of surgery deals with such elderly, debilitated or profoundly ill patients. For these reasons the use of evipal in the field is of particular interest and merits special scrutiny.

*Used to supplement local or spinal anesthesia.

Table 1 gives a list of the operative procedures which have been performed under intravenous evipal anesthesia. The technic of administration was identical with that previously outlined.² As might be expected, there was a ratio of 3 males

to 1 female in this series. The youngest patient was nine years of age, the oldest eighty-five. The patients in the younger group required distinctly more anesthetic than did those in the older group. Thus the average dose required for cystoscopic examination in patients in the third and fourth decades of life was 8 cc., whereas in the seventh and eighth decades it was 4.5 cc. Although age is a guide to the amount of anesthetic required, individual idiosyncrasy to the drug always makes the fractional method of administration imperative.

The largest dose of evipal used in this series was 28 cc. In this instance satisfactory anesthesia was obtained with difficulty and lasted only twenty minutes. After the operation, however, the patient remained comatose for four hours. We now feel that it is a mistake to continue the drug in a patient who is obviously highly resistant to it, if satisfactory anesthesia is not obtained with 10 cc., another anesthetic had best be used. However, if satisfactory anesthesia is obtained with 10 cc. but the operative procedure is prolonged, we have no hesitancy in maintaining the anesthesia with repeated doses of evipal. An amount larger than 15 cc. is seldom used. In 1 case in our series excellent anesthesia was maintained for fifty minutes with the use of only 9 cc. The average dose was 7.3 cc.

Sixty-three cystoscopies have been performed under evipal anesthesia. In 62 of them the anesthesia was highly satisfactory. In only 1 case, that of a child of nine, was the anesthesia of a duration insufficient to permit a satisfactory examination. In young, excitable patients, and in cases where painful instrumentation, such as dilatation of a urethral stricture, is indicated, preliminary medication with 15 mg. ($\frac{1}{4}$ gr.) of morphine is always given hypodermically. Spasmodic coughing during cystoscopy under evipal anesthesia has been reported,³ but we have had no difficulty in this respect. In our hands evipal has proved a safe and efficient method of inducing narcosis, the rapid, smooth induction, the ease of administration and the usually prompt recovery render it ideal. It must be emphasized, however, that the drug is a general anesthetic and must not be used unless the necessary personnel and equipment to care for the patient are available. An assistant in addition to the one administering the anesthetic

an Ace or Bender bandage. Dressings are renewed when indicated, but the bandage is continuously applied during the first two weeks, as by this maneuver the stump is more rapidly shaped and accumulation of serum is prevented. The use of this type of support is a valuable aid in rapid mobilization of the patient, and makes possible earlier application of the prosthesis. Care is also exercised to maintain the stump in the position of complete extension at the hip joint for progressively longer intervals each day, in order to prevent hip-flexion deformity.

The next step is that of fitting the pylon, a temporary appliance designed to shape the stump more rapidly for the eventual permanent prosthesis, and also to hasten the patient's discharge from the hospital. Figure 5a shows the wearing of

Figure 4 Postoperative photograph illustrating the length of the thigh stump as compared with the non-operated leg. The patient walks well with a pylon (Fig 5b).

this pylon. It means less immediate expense to the patient, and in the hands of an expert artificial-limb maker permits necessary adjustments during the ensuing months until the patient can be fitted with a permanent artificial leg. This pylon has the further advantage that if the patient cannot afford an artificial leg he can continue to walk with the pylon most satisfactorily. As a rule, the pylon is applied and the patient starts weight-bearing thereon by the end of the second postoperative week, occasionally in seven to ten days. The pylon is worn three months, or until no further shrinkage of the stump occurs. A permanent prosthesis can then be measured and fitted.

SUMMARY

A technic employed for low-thigh amputation is described. By this term is understood division

of the distal femur a few centimeters above the proximal cartilaginous margin on the anterior femoral surface.

This type of low thigh amputation is preferred to the Gritti-Stokes operation when treating old patients, particularly those individuals with advanced peripheral vascular disease or diabetic gangrene of the lower leg and foot. The procedure is simpler and safer, there is consistent primary

Figure 5 a Photograph of a patient fitted with a pylon, showing details of this prosthesis.

b Similar photograph (compare with Fig 4).

The pylon is applied between the tenth and the fourteenth postoperative days. It is a temporary prosthesis designed to shape the stump rapidly for fitting with the permanent artificial leg, and permits the patient's discharge from the hospital.

union, weight can be borne on the end of the stump, osteogenesis—patella to femur—is not required, and finally the resulting stump affords excellent leverage for a prosthesis.

Thirty-eight amputations have been performed, with 1 death two months after operation, due to rupture of an aneurysm of the abdominal aorta.

HUMAN AUTONOMIC PHARMACOLOGY

XVI Benzedrine Sulfate as an Aid in the Treatment of Obesity

MARK F LESSES, M.D.,* AND ABRAHAM MYERSON, M.D.†

BOSTON

WHEN energy intake in the form of food is greater than energy output, the excess potential energy is stored as body fat. If imbalance between food intake and energy output occurs, a change in weight must take place, whether it is to be a gain or a loss depends on the direction of the imbalance. From this point of view, the cause of obesity may be a defect of the appetite-regulating mechanism, rather than an alteration of metabolism. The perfect appetite mechanism will adjust itself to all changes of energy output, or metabolism, by a corresponding change in energy, or food intake, and thus the body will maintain its usual weight. Defect of the appetite mechanism will create imbalance in the energy output-intake relation, and a change in weight will result.

The factors which govern the appetite may be divided into the following groups: (1) physical status, particularly with reference to the endocrine glands, (2) social habits, and (3) psychologic influences. The effect of physical status on the appetite may be considered under the two aspects of disturbances due to acute or chronic organic disease, and disturbances due to metabolic abnormality as mediated through the endocrine glands. With regard to the former, little comment is needed, as the appetite disturbance of the sick is a matter of common knowledge. With regard to metabolic abnormalities, the bulimia of hyperthyroidism and the anorexia of Addison's disease may be mentioned as contrasting pictures. A more subtle disturbance of metabolism, mediated especially through the pituitary gland, has been invoked by many writers from von Norden onward, and has given rise to the concept of exogenous versus endogenous obesity.¹

In this connection, the work of Newburgh and his associates² shows that energy exchange is in no way different in a proved case of pituitary disease (Cushing's syndrome) from what it is in normal persons. The loss in weight caused by any given reducing diet may be predicted for any period with great exactness. Furthermore, in patients suffering from myxedema, where the depression in energy metabolism is greater than it is in

any other disease, striking obesity is the exception.

All visceral functions, including the appetites, are strongly modified by social habits. The appetite for food and eating have become almost as much social as they have physiologic and psychologic. People eat without particular desire under the influence of social feeling, as at parties and banquets. They are also forced to defer eating when the desire for food is very great, because of social conventions as to the serving of meals. In addition, the social and economic environment makes food and drink easily accessible to many without physical exertion.^{3, 4}

The relation of physiologic, pathologic and sociologic phenomena to the causation and maintenance of obesity having been pointed out, there remains for discussion the effect on the appetite of numerous psychologic influences. In previous papers,^{3, 4, 5} one of us (A. M.) has described a syndrome as part of the neurosis known as anhedonia. This symptom complex consists in a diminution, even to the point of disappearance or antagonism, of satisfactions normally obtained from life activities, and in a loss or distortion of the appetites and desires. The appetites involved are hunger, thirst and sex, desire for rest and recuperation, and desire for social relations, work and entertainment.

When satisfaction becomes impaired and there is no corresponding diminution in appetite, as is the case in the earlier stages of anhedonia, there is a restless seeking for stimulation in order to secure the longed-for satisfaction. The mood becomes unpleasant, and the expression of it may take many forms. One of such expressions, commonly seen in sedentary persons, is frequent eating. People who are restless because their lives are unsatisfied may be seen nibbling candy, nuts, crackers or the like. The ingestion of food becomes in a certain measure an escape. Food is easily obtained, and eating is often merely a something-to-do which has become a prime need.

The etiology of obesity and treatment of the obese person therefore appear to involve a careful consideration of the anhedonic syndrome, since in many such patients there is an associated neurosis of varying degree. A similar concept has been elaborated by Newburgh and his associates,⁶ who have pointed out that obesity is in the main the outcome of a perverted habit and that there is "dull-

must be present, and a supply of oxygen, carbon dioxide and coramin must be on hand

In the operating room evipal has proved equally efficacious. It is well suited for such procedures as excision of a hydrocele, incision and drainage of abscesses, implantation of radium and transurethral prostatic resection. It is particularly valuable as a supplement to local or spinal anesthesia. In young individuals, on the other hand, the relaxation is frequently inadequate for operations on the genitals. For this reason we feel that for circumcision evipal is not so satisfactory as gas-oxygen or even local anesthesia.

Contraindications to the use of evipal sodium have not been clearly defined. In our previous paper we listed them as liver damage, low blood pressure, the presence or imminence of shock, marked debilitation and asthma. There are certain other conditions frequently encountered in patients with urologic symptoms which require special consideration, such as sepsis, hypertension, cardiac or renal insufficiency, anemia and senility. In our series 30 patients were profoundly septic, of these, 17 cases were acute and 13 chronic. Long-standing, severe urinary sepsis is in our opinion a contraindication. This statement is based on the fact that in such cases the recovery period was frequently greatly prolonged, even after small doses. This prolonged period of coma, often lasting several hours, may predispose to pulmonary complications. Acute infection, on the other hand, presents no contraindication, except that larger doses of the drug may be necessary, and here again, with increasing doses, one finds a proportionately greater increase in the duration of the recovery period.

Hypertension in the absence of cardiac failure is no contraindication to the use of evipal. There were no untoward reactions in 8 of our patients, who had a systolic blood pressure of over 200 and a diastolic pressure of over 100. But it should be remembered that evipal may cause alarming falls in blood pressure, and in major operative procedures this may predispose to shock or collapse. The finding of an enlarged heart or cardiac murmurs does not prohibit the use of evipal but decompensation is a definite contraindication. We have never used evipal in the presence of cardiac failure, but this has been done and fatalities have been reported.⁴

Patients with renal insufficiency may be divided into two groups, acute and chronic. In the acute cases we believe that the use of evipal had best be avoided. In 2 such cases we have noted profound depth of anesthesia and a markedly delayed recovery. One patient remained unresponsive for thirty-

six hours after the administration of 9 cc. Chronic renal insufficiency, however, seems to be less dangerous. In our series, 13 patients had renal insufficiency as evidenced by a diminished phenolsulfonphthalein excretion and an elevated blood nonprotein nitrogen. These patients received evipal in doses of from 4 to 10 cc without untoward reactions. Thirty-two patients with diminished phenolsulfonphthalein excretion but with normal blood nonprotein nitrogen received evipal in doses of from 5 to 12 cc. In this group, also, no ill-effects from the anesthetic were noted. Inasmuch as evipal is often desirable for cystoscopic examinations when determination of renal function is necessary, it is essential to know whether it produces a temporary cessation of renal function. In patients with normal renal function we have observed no delay in the appearance time of phenolsulfonphthalein or indigo carmine injected intravenously during evipal anesthesia. Finally, it may be noted that we have given evipal to 3 patients with chronic nephritis and have observed no ill-effects. This apparent immunity of the kidney suggests that as a basal anesthetic in patients with renal damage evipal sodium may possess advantages over avertin.

Anemia or senility per se constitutes no contraindication to evipal. In 11 cases the red blood-cell count was between 1.8 and 3.5 million, but no unfavorable reactions occurred. It is true, however, that in such individuals a smaller dose is adequate. We have given the drug in small doses without complications to 12 patients over seventy years of age.

SUMMARY

Intravenous evipal anesthesia has proved highly satisfactory in urologic practice at the Peter Bent Brigham Hospital. It possesses the advantages of ease of administration, rapid induction and, usually, a prompt recovery. Acute or moderate degrees of chronic sepsis, hypertension, chronic myocarditis without cardiac failure, chronic renal insufficiency, anemia and senility have not proved to be contraindications to the use of evipal. It must always be employed with caution and under controlled conditions. Long-standing profound sepsis, acute nitrogenous retention, cardiac failure and liver disease, on the other hand, are absolute contraindications to its use.

visit, in order to prevent dangerous self-medication. No patient was given a prescription for the drug or was told its name.

Tolerance to the drug, so far as its effect on the appetite was concerned, did not seem to develop, for substitution of placebo tablets or omission of the drug always caused a return of increased appetite, even after months of administration.

Out of the group of 17 cases, the complete histories of 8 are given below. Table 1 gives the

factual data for the entire group. Although we here stress the utilization of benzedrine in cases of obesity which are associated with varying degrees of anhedonia and neurosis, the drug was found to be of as much benefit in cases of obesity without any obvious neurotic background, such as a case associated with narcolepsy and several cases with endocrine stigmas.

CASE REPORTS

Case 1 (obesity with psychoneurosis). A housewife of 24 complained of being overweight and of abnormal fatigability. She had gained 25 lb since the birth of her baby 7 months before. For over a year she had noted increased fatigue, particularly on wakening in the morning. The past history was otherwise negative.

The height was 62 in. and the weight 169 lb (50 lb overweight). There was no deviation from normal except for the generalized obesity. The blood pressure was 110/64. The urine was free of albumin, sugar and abnormalities of the sediment.

The patient was placed on the standard low-calorie diet. She did not return again until 11 months later, when she weighed 171 lb. She stated that she felt tired and sleepy all the time, had become very nervous and had frequent crying spells. Examination at this time revealed no change from the previous one. The blood pressure was 110/60.

In view of the fact that the patient was suffering from a psychoneurosis, she was given both stimulating and sedative therapy. She was placed on benzedrine sulfate, 5 mg on arising, 5 mg at noon and 2.5 mg at 5 p. m., and Amytal (isoamylethyl barbituric acid), 15 mg at noon, supper and bedtime. In addition, she was given the standard low-calorie diet. During the course of the next month she was seen at weekly intervals and showed a weight loss of 16 lb. Her nervousness gradually decreased,

her crying spells disappeared and she stopped munching between meals. She had no difficulty in getting a satisfactory night's sleep. She stated, "I am not hungry any more." For the first time in her life, however, she became slightly constipated. During this period the blood pressure and pulse rate remained unaltered.

At the close of the 1st month of therapy the patient was given a 2 weeks supply of the tablets and told to return at that time. This she was unable to do, so that she was not seen again until 6 weeks later. At this visit she stated that following the omission of the benzedrine tablets she had had a marked increase in appetite. I kept nibbling all day. When I take the tablets [of benzedrine] I have to force myself to eat. Whereas she had lost 16 lb in her 1st month of treatment, during the subsequent 6 weeks she lost only 5 lb. During the period of benzedrine therapy, she finally attained a dosage of 10 mg on rising, 7.5 mg at noon and 5 mg at 5 p. m. The tablets of isoamylethyl barbituric acid were omitted when the nervous symptoms disappeared. Following the resumption of benzedrine therapy the loss in weight continued, and in the final 6 weeks she lost 8 lb. During 2 of these weeks she again missed an appointment and was without benzedrine for 2 weeks. Upon cessation of the benzedrine her appetite became "tremendous," and she ate so much that there was a temporary gain in weight. At her last visit she stated that she felt perfectly well, and physical examination disclosed no abnormality. She lost 29 lb during the 17 weeks of observation.

Case 2 (obesity with psychoneurosis). A housewife of 32 complained of being overweight and of weakness, easy fatigability and tiredness. She had always been overweight, but since her marriage 8 years previously her weight had increased from 165 to 212 lb without apparent cause. Her appetite had always been very good, and she ate a great deal between meals. She had had weakness and easy fatigability for the past year. Six and a half years previously, following the birth of her first child, she had had a nervous breakdown. During that period she lost 35 lb, so that her weight dropped to 140 lb. Since then her weight had increased to its present figure. The cause of the breakdown was not known to her. She said that at that time, "I could not eat. I could not look at food. I had terrible and crazy thoughts, nothing interested me. I did not care for anything."

I had frequent ideas of falling. She was ill for about a year with this condition, and then gradually improved. She had always slept well but awoke every morning with a tired feeling and without a normal sensation of restfulness. During the day her fatigue occurred without relation to exertion. The rest of the history was irrelevant.

The height was 61 in. and the weight 210 lb (87 lb overweight). The patient showed a centripetal obesity, the fat being chiefly over the buttocks, thighs, abdomen and upper arms. The hands and feet were small and in proportion to the height. The blood pressure was 120/80. The rest of the examination was normal. The hemoglobin was 60 per cent (Sahli) with 4,100,000 red blood cells per cu mm. The blood smear showed moderate hypochromia of the red cells, but no abnormalities of the white cells. A sugar-tolerance test, following the ingestion of 100 gm. of dextrose in 20 per cent solution, showed no glycosuria up to 2 hours. The blood sugar at the end of the 2nd hour was 72 mg per cent (Folin-Wu method).

This patient was placed on the standard low-calorie diet and was given benzedrine sulfate, 7.5 mg on arising, 5 mg at noon and 5 mg at 5 p. m. This was gradually increased to 10 mg on rising, 10 mg at noon and 7.5 mg at 5 p. m. The patient was observed at weekly intervals for 15 weeks,

ing of the acuity of the sensations, weak will and a pleasure-seeking outlook upon life"

To attack the syndrome of anhedonic obesity through the psychologic mechanisms involved, in an effort to cut down the unphysiologic desire for food, seems more rational than the usual therapeutic efforts, which are largely aimed at increasing the metabolism through drug administration—for example, thyroid extract or dinitrophenol—or exercise, or decreasing the food intake by strenuous dieting. The latter methods are successful, but do nothing to eliminate the cause, that is, the anhedonia. This neurotic relation is shown by the easy fatigability of the obese, which is, we believe, due not so much to the excessive weight that must be carried as to the neurotic factors which have produced and are sustaining the obese state. This is well attested by the fact that in many of the cases to be described the fatigue was not that seen after physical effort, unusual or customary, as in normal persons, but was the characteristic "morning tiredness," occurring even without the expenditure of energy, which is seen in the neurotic and the physically sick. Thus, the excess food ingestion of the anhedonic obese person rarely occurs in the morning, when desire and mood are especially low, but comes later in the day and in the evening.

Benzedrine sulfate (phenylisopropylamine) is an advantageous drug with which to attack the problem. Its action is primarily that of a sympathetic stimulant, chemically speaking, it is an adrenergic drug. Thus, on the eye and the vascular system it has the classic effects of sympathetic stimulation, it relaxes the spasm of the gastrointestinal tract,⁸ and tends to decrease the gastric juice while increasing its acidity.⁹ Its effects on the mood, on the sensation of energy and its output, and on the gastrointestinal tract offered the desired psychophysiologic action. Given in small doses, below the point where it produces marked changes in the visceral activities, benzedrine sulfate prevents sleepiness and drowsiness, this is the basis for its use in narcolepsy.¹⁰ The dissipation of the feeling of fatigue and the beneficial influence on state of mind effected by this drug in both normal and neurotic persons have been established by recent reports.^{11 12 13} Because of these psychologic effects the urge to eat as a means of filling out an empty existence is lessened.

The direct effect of benzedrine sulfate on the appetite for food is of primary importance in the group of cases to be discussed. That it seems to cause a loss in weight has already been noted by Nathanson.¹² Evidence of its ability to reduce the appetite will be adduced below.

A group of 17 unselected and consecutive private patients, with a primary complaint of obesity, were placed after initial study on a measured, unweighed diet of about 1400 calories, with an approximate composition of protein 69 gm., fat 57 gm., carbohydrate 150 gm., calcium 0.65 gm. and iron 0.014 gm. No further instructions as to the diet were given after the first visit. No patient was urged to follow the diet, or to do otherwise than obey his natural desire. All patients were observed at intervals of from seven to fourteen days, and at each visit the weight, blood pressure and pulse rate were observed. All reported symptoms were noted, and leading questions which might obscure the subjective effect of the drug were avoided. Prolonged observation by Myerson and his associates¹⁴ indicated that in man the elevation of the blood pressure was the most toxic effect of benzedrine. This hypertensive effect was rarely associated with an increase in the pulse rate. The dosage of benzedrine utilized never caused blood-pressure elevation, even in patients with hypertension. Subjectively, the more important criteria of benzedrine toxicity were nervousness, a jittery sensation and nocturnal insomnia. Here again, careful regulation of the dosage prevented these reactions.

Benzedrine sulfate is distributed in 10-mg tablets, which are scored so that they may be broken into quarters, each representing 2.5 mg. The most satisfactory plan of treatment was to give three doses daily—a large dose in the morning immediately on waking or rising, a moderate dose at noon and a small or moderate dose in the late afternoon. As a rule, we started with 7.5 mg on arising, 5 mg at noon, and 2.5 mg at 5 p.m. This dosage was gradually increased from week to week as the need arose, but the dosage was stopped well short of the point at which nervousness or nocturnal insomnia was produced. Ordinarily, an increase of 5 mg weekly caused no untoward symptoms. The largest dose given any patient was 30 mg daily, divided into three unequal doses (12.5 mg on arising, 10 mg at noon and 7.5 mg at 5 p.m.).

This dosage schedule accomplished two desirable results: the largest dose was given in the morning, when the feeling of the energy was at its lowest, and the smallest was given in the afternoon, when the energy output was increasing and the time for sleep was approaching. In occasional cases, where the appetite for excess ingestion of food during the evening was uncontrollable, the plan of giving a large dose in the morning, a small dose at noon, and a moderate or large dose at 5 p.m. was tried with some success, particularly if insomnia did not follow. All patients were supplied with only enough tablets to last until the next

overweight) Except for generalized obesity, the examination was negative. The blood pressure was 126/84. The urine showed no albumin, sugar or abnormalities of sediment. The hemoglobin was 70 per cent (Sahli), the red blood cells numbered 4,000,000 per cu mm, and the smear showed normal red and white blood cells.

This patient was placed on the standard low-calorie diet. She was given a mild hypnotic (sodium bromide) to aid her in securing sound sleep, and a fairly large dose of benzedrine in the morning immediately on rising in order to break up the habit of returning to sleep. On this regimen she showed a weight loss of 32 lb in 21 weeks. The blood pressure ranged from 140/90 to 106/76, tending to drop during observation. During the course of treatment she found it very easy to follow the diet. Moreover, the morning benzedrine tablet eliminated the desire to go back to bed at that time. She had no difficulty in falling asleep at night, and after a few nights omitted the hypnotic entirely. Her feeling of energy was markedly increased, and her appetite was noticeably less. She became slightly constipated. There were no untoward symptoms, except occasional headaches, which were no more frequent than those she had occasionally had before taking the benzedrine, and were of the same nature. Toward the end of the period of study the patient developed an increase in appetite during the evening. To counteract this, the benzedrine medication was rearranged so that she took 5 mg on rising, 2.5 mg at noon and 7.5 mg at 5 p m. This rearrangement did not seriously interfere with sleep, and it helped in decreasing the excessive evening appetite. During a 2 weeks period the patient was given placebo tablets and gained 4 lb. She noted a return of sleep spells and marked increase in appetite.

Case 9 (obesity following subtotal thyroidectomy) A houseworker of 38 complained of being overweight. Two years before her first visit she had had a subtotal thyroidectomy for hyperthyroidism, from which she had completely recovered. In the 2 years following the operation she had gained 35 lb, mostly in the 1st year. The rest of the history was irrelevant.

The height was 61 in. and the weight 150 lb (27 lb overweight). There was generalized obesity. The eyes were prominent but showed no lid lag. The skin over the elbows and over the posterior surfaces of the upper arms was somewhat dry and rough. The hair was slightly coarse. The neck showed a well healed thyroidectomy scar, with a small amount of thyroid tissue palpable in both lobes. There was slight puffiness under the eyelids. The urine was free of albumin, sugar and abnormalities of the sediment. The hemoglobin was 78 per cent (Sahli), the red-blood-cell count was 4,650,000, the smear was normal, the basal metabolic rate was -3 per cent (Mayo standards) in a satisfactory test. The blood pressure was 110/80.

There was an apparent disturbance in the appetite-regulating mechanism, as evidenced by a constant craving for food. There was no clear-cut clinical evidence of myxedema, and the basal metabolic rate bore out this negative impression. She was therefore placed on the standard low-calorie diet and was given benzedrine sulfate, 5 mg on rising, 5 mg at noon and 2.5 mg at 5 p m. This dosage was gradually increased until she was receiving 10 mg on rising, 7.5 mg at noon and 5 mg at 5 p m. Her highest blood-pressure reading during the course of treatment was 126/84. The pulse rate was always within normal limits. She was seen at biweekly intervals during the next 19 weeks, during which time she lost 27 lb. There were no untoward symptoms throughout the course of observation. Her sleep was not interfered with and she found it very easy to follow the diet. Her appetite

was good, but she lost the craving for food. She was discharged after 19 weeks of treatment because she had attained her normal weight. The final physical examination showed no abnormalities.

Case 10 (obesity) A housewife of 45 complained of being overweight and of easy fatigability. She had been overweight all her life. Twenty years previously, at the time of her marriage, she weighed 170 lb. Her appetite had always been unusually good. She had dieted many times but without any success, and in fact within the preceding months had gained 5 lb. The rest of the past, marital and family histories was irrelevant.

The height was 65 in. and the weight 231 lb (95 lb overweight). There was generalized distribution of the excess fat except for the breasts, which were normal in size. The blood pressure was 152/78. The heart was not enlarged, but a barely audible systolic murmur was heard over the apex. The rest of the examination was normal. The urine was free of albumin, sugar and abnormalities of sediment.

The patient was placed on the standard low-calorie diet and was given benzedrine, 5 mg on rising, 2.5 mg in mid morning and 2.5 mg at noon. This dosage was gradually increased and the time of administration was rearranged, so that eventually she was taking 12.5 mg on rising, 10 mg at noon and 5 mg at 5 p m. She was seen at intervals of 10 days over a period of 25 weeks, and during that time lost 48 lb. The initial blood pressure, which was somewhat elevated, showed a normal reading on subsequent visits, and on several occasions went as low as 104/70. During the period of observation she noted a decreased appetite and an increased feeling of energy. There were no other subjective changes. She found it easy to follow the diet. For several weeks the rate of loss in weight was so marked that the diet had to be increased. At no time was there interference with the ability to fall asleep or stay asleep. During one 10-day interval, blank placebo tablets were substituted for the benzedrine sulfate. The patient gained weight in that period and noted a marked return of appetite and "extreme hunger."

Case 12 (obesity—failure of benzedrine to aid in reducing weight) This patient, a student of 20, had been under intermittent observation for a period of 3 years. She had undergone a previous course of reducing with diet and thyroid extract quite satisfactorily, attaining a final weight of 135 lb., 2½ years before the present period of study. In the interim she had gradually gained weight to a maximum of 177 lb. This gain occurred while she was working as a cook.

The height was 63 in. and the weight 176 lb (48 lb overweight). Examination showed centripetal obesity, the excess adiposity being largely confined to the middle third of the body, and most marked over the buttocks and upper thighs. The breasts were small and pubescent. The hair distribution was normal. The rest of the examination was normal. The basal metabolic rate in two determinations was ± 0 per cent (Mayo standards). The blood pressure was 94/60.

The patient was placed on the standard low-calorie diet and was given benzedrine sulfate, 7.5 mg on rising, 5 mg at noon and 2.5 mg at 5 p m. The dosage was gradually increased to 10 mg on rising, 7.5 mg at noon and 5 mg at 5 p m. Over a period of 10 weeks there was no change in weight. Numerous unpleasant symptoms were complained of— inability to breathe deeply, marked nervousness, constipation, dry cough, increased irritability with difficulty in falling asleep and marked fatigue. Further study of the emotional background dis-

during which time she lost 17 lb. Her fatigue disappeared, although her sense of well being was not particularly improved. There was a significant decrease in the appetite. The blood pressure remained within normal limits. This patient is still under observation.

Case 3 (obesity with psychoneurosis) A housewife of 38 complained of being overweight and of nervousness. She had been overweight most of her life. Seventeen years previously, at the time of her marriage, she had weighed 140 lb, and since then had gradually gained in weight. One year previously she had undergone a tonsillectomy, and had gained 15 lb shortly thereafter. Her appetite had always been excellent, but she was not accustomed to eating between meals. She stated that she had always done her own cooking and did do a good deal of tasting. Recently she had become accustomed to sleeping 10 or 11 hours at night. She had been nervous and easily irritable since her husband had been diagnosed as having heart trouble. Her father had died of Bright's disease at the age of 52, and one brother had diabetes and heart trouble. The rest of the history was negative.

The height was 64 in. and the weight 194 lb (62 lb overweight). Except for generalized obesity, the physical examination was negative. The blood pressure was 126/80. The urine was free of albumin, sugar and abnormalities of the sediment. The hemoglobin was 78 per cent (Sahli). The basal metabolic rate in a satisfactory test was -15 per cent (Mayo standards).

The patient was placed on the standard low-calorie diet and given benzedrine sulfate, 2.5 mg on rising, 2.5 mg in mid morning and 2.5 mg at noon. The dosage was gradually increased until she was taking 10 mg on rising, 7.5 mg at noon and 5 mg at 5 p m. This patient was seen at weekly intervals for a period of 23 weeks and in that time lost 26 lb. The craving for food was lost, the nervousness and irritability became markedly decreased. She slept well, was free of all unpleasant subjective symptoms and in fact had a sense of well being. Benzedrine was omitted and placebo tablets were given for 2 weeks during the period of observation, during that time, she spontaneously stated, she had had a return of her nervousness and craving for food. During this period there was a gain in weight of 2 lb.

Case 7 (obesity with narcolepsy) A 34-year-old salesman complained of being overweight and of sleepiness. His birth weight was 16 lb and he had been continuously overweight since birth. At the age of 16 he weighed 140 lb, at the age of 19, 200 lb. His weight gradually increased until at the age of 29 he weighed over 300 lb. The weight had been stationary for the last 4 years. His appetite had always been very good, and he ate continuously throughout the day. In addition to sleeping 9 or 10 hours at night, he found himself continually falling off to sleep throughout the day whenever the opportunity presented itself. In the past history there was nothing of importance except that he had had gonorrhea 18 years before, which had apparently never cleared up, as since then he had noted a slight penile discharge intermittently. He had also had nocturia during the last 7 or 8 years, but apparently no daytime frequency or polyuria. There was no impairment of sexual desire or potency.

The height was 69 in. and the weight 316 lb (158 lb overweight). The blood pressure was 104/80. The patient was very obese, with the excess adiposity concentrated about the abdomen. There were a few red striae over the lower abdomen. The fundi showed clear and well-outlined nerve heads, normal arteries and slightly engorged veins. The mouth, throat, neck, heart and

lungs were normal. The genitalia were normal. All reflexes were normal. The urine had no albumin or sugar, but the sediment showed 10 white blood cells per high-power field, and the stained urinary sediment showed many extracellular cocci. The prostatic smear showed many pus cells and cocci. The basal metabolic rate was +8 and +10 per cent (Mayo standards) in two fairly satisfactory determinations. The blood Hinton test was negative. Blood sugars taken 1 and 2 hours after the ingestion of 100 gm. of dextrose in 20 per cent solution showed values of 174 mg per cent and 95 mg per cent respectively. A 24 hour urine was measured to exclude the possibility of diabetes insipidus and showed a volume of 3000 cc.

This patient presented two clinical problems: lethargy, almost to the point of narcolepsy, and a huge appetite, present since birth. He was placed on the standard low-calorie diet and given benzedrine sulfate, 10 mg on rising, 10 mg at noon and 5 mg at 4 p m. This dosage was later changed to 12.5 mg on rising, 10 mg at noon and 7.5 mg at 5 p m. He was seen at weekly intervals for the next 12½ weeks, during which period he lost 54 lb. He followed the diet with ease, and stated voluntarily that his appetite was markedly decreased, and that he had become more active physically and felt very well. His daytime drowsiness disappeared, although he continued to sleep well at night. No unusual symptoms presented themselves, except for slight constipation. He stated that he was seldom hungry and was satisfied with the amount of food allowed in the diet. For 1 week during the period of observation he did not take the benzedrine tablets, and during that period there was no loss in weight and the narcolepsy returned. Upon resumption of the benzedrine tablets the drowsiness disappeared and the loss in weight continued. Later on the patient stopped all treatment for 1 month and regained 11 lb in that time. Upon resumption of benzedrine the loss in weight continued as before.

Case 8 (obesity with hypomenorrhea) A housewife of 27 complained of being overweight and of irregular menstruation, shortness of breath, backache and nervousness. In the 6 months preceding her first visit she had gained 40 lb. For many years before that her weight had been constant. She did not know the cause of her gain in weight, and felt sure it was not due to overeating or any change in activity. Careful inquiry disclosed one significant change in her daily habits which was a factor. Shortly before the onset of her gain in weight, her 5-year old son had started to attend school. Whereas previously, having once risen in the morning she was accustomed to staying up, she had now developed the habit of going back to bed for several hours after sending her son to school. Since her regular sleeping habits had not changed in any way, this gave her several hours more of rest every day. She had always been a light sleeper, accustomed to going to bed late and rising early because of her children.

During the period of gain in weight, her menses, which had previously occurred at 28-day intervals, came from 1 to 3 weeks late and were of short duration, with a more scanty and painful flow. During that time she had also noted some low back pain, usually made worse by prolonged sitting. She had consulted a gynecologist, who found no pelvic abnormality. The shortness of breath was of only a few months' duration and occurred following the gain in weight. Her past history showed that she had been pregnant twice and on each occasion had developed hypertension, which was said to have disappeared at the end of the pregnancy.

The height was 65 in. and the weight 189 lb (53 lb

CASE 24031

PRESENTATION OF CASE

A sixty-four-year-old, white, married Swedish gardener entered the hospital with a complaint of jaundice of two months' duration.

He had always been well until two months before entry, when he noticed gradually increasing jaundice of his skin, unaccompanied by pain, chills or gastrointestinal symptoms. As the jaundice became deeper, he noticed that he bruised easily. He developed severe pruritus which caused him to scratch his skin, producing many excoriations. Six weeks before entry he noticed that his stools were slightly paler than normal, and by the time he entered the hospital they were clay colored. During this time his urine became mahogany colored. During the three days before entry he had passed small amounts of bright-red blood in his stools but previously he had had a barium enema. He had had no other symptoms of any kind except anorexia and loss of 25 lb in weight.

During all his adult life he had drunk alcoholic beverages daily. He had taken very little during prohibition, but after that for the four years before entry he had had two or three beers and one whiskey eggnog every day. His past history was otherwise negative. He denied ever having had syphilis.

His wife and two children were living and well, and there had been no miscarriages.

Physical examination revealed a well-developed, fairly well-nourished deeply jaundiced man. He was in excellent spirits and felt well except for severe pruritus. There were numerous small excoriations distributed over practically the entire body. The heart and lungs were negative, and the blood pressure was 125 systolic, 85 diastolic. The liver edge was easily palpable three fingerbreadths below the costal margin and was smooth and non-tender. There was no tenderness anywhere in the abdomen, and no masses were palpable. The spleen could not be felt. There were a few shotty non-tender lymph nodes in the inguinal regions. There were a few external hemorrhoids, and the prostate was normal.

The temperature was 98°F., the pulse 70. The respirations were 20.

The urine had a specific gravity of 1.013, con-

tained the slightest possible trace of albumin and 4+ bile and showed 2 red cells and occasional white cells per high-power field in the sediment. The blood showed a red cell count of 3,880,000 with 60 per cent hemoglobin. The white cell count was 7100, 73 per cent polymorphonuclears. The bleeding time was one and a half minutes. The clotting time varied from fifteen to twenty-one minutes, and there was very little clot retraction. The stool was guaiac negative on two occasions. A van den Bergh was 38.2 mg per cent, biphasic. A blood Hinton test was negative once and doubtful once, and the Wassermann was negative. A Takata-Ara test was negative.

A gastrointestinal x-ray series showed small indefinite filling defects of the esophagus suggestive but not characteristic of varices. The stomach and duodenum appeared normal. The shadow of the liver was moderately enlarged, but there was no evidence of enlargement of the spleen. An x-ray of the chest showed no evidence of metastatic malignancy, but there were two or three indefinite areas of density at the right border of the heart which could have been enlarged glands. Many calcified nodes were present.

On the seventh day duodenal drainage was attempted. An x-ray showed the tip of the catheter apparently lying in the antrum of the stomach. The material aspirated gave a positive test for bile and a questionably positive guaiac test. Soon afterward the tube was passed successfully into the duodenum and bile-stained material was aspirated. The sediment from this specimen contained 4 or 5 red cells per high-power field, and occasional white cells, some in clumps. On the following day the duodenal contents were bile negative, and the blood van den Bergh was reported as 57 mg per cent, biphasic. About that time he complained of pain in the left shoulder, and examination revealed a tender mass measuring 2.5 by 3 cm in diameter just medial to the scapula. By the eleventh day this mass had increased in size to a diameter of about 8 cm and was sufficiently painful to interfere with his sleep. It was not red or fluctuant. On the following day he had a moderate nosebleed and some bleeding from an excoriation on the back of his neck. The bleeding time was two minutes and the clotting time varied from fifteen to thirty-one minutes. The clot retraction was normal. The white-cell count of the blood was 12,800, with 68 per cent polymorphonuclears, but his temperature remained normal. A laparotomy was performed on the fourteenth day after two pre-operative transfusions.

DIFFERENTIAL DIAGNOSIS

DR. MARSHALL K. BARTLETT: Our problem in this case concerns a man of sixty-four who has

closed that just before coming under observation the patient had gone through an unhappy love affair, which had left her quite depressed. She stated that during her periods of greatest depression she ate large amounts of food in an effort to compensate for her disturbed emotional state. The benzedrine in this instance had of course failed to restore the feeling of well-being and of increased energy, which is often essential to its action in reducing the appetite. Appropriate psychotherapy in this patient eventually restored some degree of emotional calm, and the administration of benzedrine during this phase effected moderate loss in weight without unpleasant symptoms.

Benzedrine sulfate is an important aid in the treatment of obesity of any type, on the one hand it decreases the appetite, and on the other so increases the sense of well-being and of energy that physical activity is spontaneously increased. Its proper place in the treatment of obesity is as an adjuvant. In association with a properly selected low-caloric diet, it helps the patient to follow the diet with greater ease by abolishing the neurotic and ill-timed craving for foods which plays so important a role in the genesis and maintenance of the obesity. Our experience, however, shows that benzedrine will not so readily effect weight reduction when it does not lift the patient's mood and increase his sense of well-being. In the more profound neuroses where elevation of mood is not in any permanent way affected by the drug and where the appetite is already absent, benzedrine sulfate is not indicated. Its use in the neurotic obese, therefore, is largely limited to those cases associated with what we have here termed a mild anhedonic state.

SUMMARY AND CONCLUSIONS

1 Obesity is often due to a defect in the mood which upsets the appetite-regulating mechanism. In such cases increased eating, which does not represent true hunger, takes place in order to offset and compensate for the disturbed mood.

2 The commonest cause of this disturbance in appetite is the anhedonia associated with psychoneurosis.

3 Benzedrine sulfate, by improving the anhedonic state, acts as an aid in obese neurotic persons.

4 Benzedrine sulfate has a direct effect in depressing the appetite and in increasing physical activity, and is therefore useful in any type of obesity.

5 In a group of obese patients suffering from associated psychoneuroses, endocrine disease and narcolepsy, benzedrine sulfate has been used as an adjuvant to weight reduction without development of any toxic signs or symptoms, during periods ranging from six to twenty-five weeks.

At the time of going to press benzedrine sulfate has been used in the treatment of 40 obese patients over periods of from three to nine months. The above conclusions are substantiated with regard to benefit and lack of toxicity in the indicated dosage.

371 Commonwealth Avenue.

PATHOLOGICAL DISCUSSION

DR. MALLORY The autopsy showed a very large liver. It was very pale green at autopsy, and as I understand it, it was a dark green at the time of operation.

DR. CROVE Yes, it was.

DR. MALLORY That would be a very unusual finding for toxic hepatitis. One almost always finds yellow jaundice of the liver rather than green jaundice with an acute intrahepatic lesion. That certainly is true at autopsy and I believe it is at operation. Would you agree, Dr. Allen?

DR. ARTHUR W. ALLEN Yes.

DR. MALLORY The common bile duct, the cystic duct and the gall bladder proved to be entirely negative. When we reached the point where the two hepatic ducts join we could feel some slightly firm tissue practically in the hilus of the liver. In gross opinion in the laboratory was divided as to whether it was an inflammatory stricture or a neoplasm. On the whole most of us after palpating the lesion favored inflammatory stricture, but that would be quite extraordinary in a patient who had never been operated on and who had had no evidence of gallstones. Microscopic examination showed primary carcinoma of the bile ducts evidently arising at the juncture of the two hepatic ducts so high up that any form of anastomosis would have been impossible.

A PHYSICIAN Did you look at his shoulder?

DR. MALLORY We did not turn the body over.

DR. RICHARD B. KING In what proportion of cases of carcinoma of the pancreas can you feel a mass?

DR. MALLORY I should guess that two thirds of the time you might feel one.

DR. CROVE Could the blood in the duodenal content have come from this tumor?

DR. MALLORY It certainly could have. I think one has to be very cautious, however, in interpreting small amounts of blood in the gastrointestinal tract of a jaundiced patient. Many of them bleed all up and down the gastrointestinal tract, without gross lesions.

CASE 24032

PRESENTATION OF CASE

A forty-eight-year-old Swedish laundryman was admitted complaining of weakness and numbness of the legs. During the two years preceding entry the patient had noticed occasional stiffness and weakness in the neck. During the same time there was slightly increasing fatigue. He recalled some difficulty in getting about in the dark because of easy loss of sense of direction. About a year before entry he began to have spells of faint-

ness although he did not lose consciousness. Six months before entry he began to have numbness of the calves, feet and posterior thighs, particularly on the right. There were also some numbness and weakness of the forearms, more on the left. Shortly afterward he had numbness and loss of taste on the left side of the tongue, although he was still able to smell with the left nostril. Three months before entry he developed morning nausea and vomiting. He attributed this to beer which he apparently had been drinking in large quantities. He discontinued the beer drinking, but the nausea and vomiting persisted. Four weeks before coming to the hospital his wife noticed asymmetry of his face due to weakness of the left side, and at this time his legs became weaker, so that he had to be very careful about walking. His neck became weaker, and his head felt heavier. He complained of blurring of vision in both eyes, although a physician told him that his eyes were normal. The patient had also noted headache, dizziness and nervousness. Weakness in the left leg caused him to stagger, particularly to the left.

At the age of six months it was noted that his left shoulder was paralyzed. Twenty years before entry he developed deafness in the left ear which was associated with hissing noises. The deafness increased until it became complete. The tinnitus disappeared several years ago.

Physical examination showed a rather thin man in no acute discomfort. The muscles of the left shoulder cradle and the deltoid and biceps were atrophied in appearance. The left upper chest was more prominent than the right. There was left fifth-nerve weakness with sensory loss on the left side of the face, skin, mucous membranes and tongue. The left corneal reflex was absent, and there was left nerve deafness. There was facial asymmetry with questionable drawing up of the muscles of the left cheek. The strength of the arms and legs appeared to be normal and equal on both sides except for evidence of old left brachial palsy. The finger-to-nose and the heel-to-knee test showed evidence of asynergia on the left side. Position sense was preserved. There was hypoalgnesia of the right arm. The pupils reacted normally to light. The triceps, biceps and radial reflexes were absent. The abdominals were present but diminished. The knee jerks were normal and symmetrical. Cremasteric reflexes were absent. The ankle jerk was present on the right, absent on the left. Plantar stimulation showed dorsiflexion of the great toe bilaterally. Caloric tests failed to elicit nystagmus on the left. There was absence of taste perception on the left side of the tongue.

The temperature, pulse and respirations were normal.

painless jaundice of two months' duration, which has steadily progressed apparently without definite fluctuation in the degree of jaundice. It seems to me that the first thing to try to decide is whether the jaundice was due to obstruction of the common duct or to an intrahepatic process of some kind. I think we can rule out syphilis on the basis of his negative blood Hinton and Wassermann tests and the absence of anything suggestive in the history.

In regard to cirrhosis of the liver, it seems to me that the only things in this case that particularly favor such a diagnosis, are the facts that he is a man with a history of prolonged alcoholic intake and that there were questionable esophageal varices by x-ray. Against cirrhosis are the short duration of the disease, its relatively rapid progress and a lack of any preceding gastrointestinal story of any kind. The spleen was not palpable, and he had no ascites that could be made out clinically, also, the jaundice was very deep and had progressed quite rapidly. So we have to assume that this man had an obstructive jaundice, and we must try to decide where the obstruction was and what caused it. For practical purposes we must differentiate gallstones and malignant neoplasm. I cannot see anything in this story in favor of gallstones except the fact that it is a more common disease than neoplasm with obstruction to the common bile duct. He has no past history suggesting gall-bladder disease. He has had no pain at any time. The jaundice has been steadily progressive from the onset until his admission, at which time he apparently had nearly complete obstruction of the common duct. Again favoring neoplasm is his rather great and rapid weight loss, 25 lb. in two months. It seems to me, then, that we have to say that the chances are overwhelmingly in favor of a malignant obstruction rather than a gallstone, although I think we cannot get around the possibility that a gallstone can do all these things. It is not so likely as neoplasm.

The best possibility is carcinoma of the head of the pancreas. What of a neoplasm involving primarily the bile duct and possibly the gall bladder? It is perfectly possible but less common. The various bleeding phenomena are perfectly explainable on the basis of jaundice. I do not feel very happy about that mass on his back, medial to the scapula, which appeared toward the end. The rapid increase in size is striking. When it was first noticed it was 3 cm. in diameter and on the eleventh day it was 8 cm., and painful. It seems to me too rapid an increase in size for a metastasis, and it must be, I suppose, an infected hematoma. So my diagnosis in this case is carcinoma of the head of the pancreas with obstruction of the common duct

with resulting jaundice and various bleeding phenomena.

DR NEIL L. CRONE: We felt more or less the way Dr Bartlett did. One thing I should like to say that might have made it easier is that the mass over the scapula at first was non-fluctuant, but as it increased in size, it became definitely fluctuant. It did not involve the skin and was never red. I shall read the note which I wrote to Dr Linton: "I believe that this man should be explored. I feel that he has carcinoma of the pancreas or bile ducts (probably the latter). I admit that cirrhosis is possible, but such a diagnosis cannot be made. Regardless of this possibility I believe exploration should be done."

The red cells in the duodenal drainage partially influenced me toward the possibility of cancer of the bile duct, furthermore, I felt that if he had carcinoma of the pancreas which had eroded through the duodenum it certainly ought to show by x-ray.

DR TRACY B. MALLORY: Were you present at the operation? Can you tell us what was found?

DR. CRONE: It is always difficult for a medical man who has not scrubbed to see much. Dr Linton found the liver enlarged and apparently rotated. The gall bladder was not distended, in fact it was quite decompressed, otherwise it appeared normal. The head and body of the pancreas were normal. The common duct was not distended, it was collapsed. No obstruction could be found. There were no stones in the gall bladder or common duct. Our impression of the liver was that it presented the appearance of acute hepatitis.

The patient died three days later without any further developments that seemed significant from the point of view of diagnosis.

CLINICAL DIAGNOSES (PREOPERATIVE)

Obstructive jaundice
Carcinoma of the head of the pancreas or of the bile ducts?
Common duct stone?

DR. BARTLETT'S DIAGNOSES

Obstructive jaundice
Carcinoma of the head of the pancreas
Hematoma of the back

ANATOMIC DIAGNOSES

Carcinoma of the extrahepatic bile ducts
Operation wound exploratory laparotomy
Hemorrhage, postoperative
Hydrohepatosis
Purpura
Hydrothorax, bilateral
Icterus

These tumors when they come to operation have a fairly uniform appearance. They are 4 cm or so in length and about 3 cm in diameter, and lie wedged against the side of the pons between the cerebellum and the posterior surface of the petrous pyramid. In all the cases which I have examined post mortem there has been extensive erosion of bone in the region of the internal acoustic meatus, with tumor extending into the inner ear. This erosion, it seems to me, has always been more extensive than it appeared in the x-ray films.

The fact that impairment of hearing and tinnitus have usually been present for several years before the onset of other symptoms may very well mean that the tumor starts near the labyrinth and extends into it long before it reaches any great size. That the deafness in this case, of twenty years' duration, was due to the tumor is,

I believe, not at all impossible. The tinnitus eventually stopped, probably owing to destruction of the labyrinth or nerve.

Curiously enough the seventh nerve, which also passes through the internal meatus, is seldom completely paralyzed and may be affected only slightly. Sensory impairment on the face, usually present when the patient is seen by a neurologist, may be accounted for by the fact that the fifth nerve is stretched over the inner anterior pole of the tumor and its inner portion is compressed between the tumor and the pons. Then, too, there is pressure against the pons which may very well affect the fifth-nerve nucleus.

The so-called cerebellar signs probably result largely from pressure on the vestibular nucleus although pressure on the cerebellum is another possible factor.

Examination of the urine showed a specific gravity of 1.020, with a slight trace of albumin. The sediment was negative. The blood gave a red cell count of 4,300,000 with a hemoglobin of 75 per cent. The white cell count was 8400, 64 per cent polymorphonuclears. A lumbar puncture done before the patient's admission to this hospital is reported to have shown a clear colorless fluid, the pressure and total protein were not recorded. A test for globulin gave a 4+ reaction. The cell count was 2 per cu mm. The spinal-fluid Wassermann test was negative. A blood Hinton test was negative.

X-rays of the skull showed definite enlargement of the left internal auditory canal. The canal was expanded throughout its entire length, the greatest enlargement being near the tip. There was no definite enlargement of the sella turcica. The clinoids were rather indistinct but showed no definite evidence of erosion.

During the succeeding week the patient showed no essential change in his condition. A craniotomy was performed on the eleventh hospital day.

DIFFERENTIAL DIAGNOSIS

DR. AUGUSTUS S. ROSE: If possible one would like to make a diagnosis of a single disease process. In this case, however, we are confronted with a process or processes which are sufficiently widespread to involve the central and peripheral nervous systems. There are very few such conditions.

The history, through symptoms of weakness and sensory disturbances, directs our attention at first to the peripheral nerves, but the physical examination shows signs of central involvement. The gradual onset of deafness with tinnitus, leading finally to complete nerve deafness, and followed by the loss of taste on the left side of the tongue and by loss of sensation on the left side of the face, with also the development of a facial asymmetry (presumably a left facial weakness), points strongly to a slowly growing tumor at the left pontine angle. The examination substantiated the history that there was loss of function of the left eighth, seventh and fifth nerves (although weakness of the face is not definitely stated). The suspicion of tumor is confirmed by the x-ray finding of enlargement of the internal auditory canal. With slow development and progression, the most likely tumor in this location is a neurofibroma, probably starting in the eighth nerve. If it is a single tumor involving all three nerves, then it is sufficiently large to explain the Babinski signs, headache, dizziness and vomiting. Involvement of the vestibular division of the eighth nerve would explain staggering to the left. Other lesions are necessary, however, to explain the subjective symptoms

(not substantiated by examination) of weakness of the neck and extremities, sensory disturbances in the arms and legs, and absent tendon jerks. These are symptoms and signs associated with disease of peripheral nerves, especially when the jerks are absent on one side and present on the other. We are not informed as to the presence or absence of a palpable tumor in the skin or along the nerve trunks, or of pigmented spots on the skin, but neurofibromas are frequently multiple, and we wonder about von Recklinghausen's disease. Yet, we are led to believe that this patient drank beer to excess, and there is no reason why a person with an acoustic neuroma should not also develop a peripheral neuritis. No information is given, however, as to the patient's diet, and these symptoms have lasted at least two years. With peripheral neuritis of two years' duration, more objective motor disturbances, such as atrophy and profound weakness of certain muscle groups, would be expected. Neurofibromas produce symptoms only by compression, and when situated on peripheral nerves must attain considerable size before much degeneration of neurons occurs. Furthermore, it is difficult to conceive of tumors on the nerves causing disappearance of tendon jerks without other signs.

The laboratory data give only negative evidence. Without more information the diagnosis must remain: (1) left pontine angle tumor, probably an acoustic neuroma, (2) neurofibromatosis (?), (3) peripheral neuritis of unknown cause (?) and (4) old left brachial-plexus injury.

PREOPERATIVE DIAGNOSIS

Left acoustic neuroma

DR. ROSE'S DIAGNOSES

Left pontine angle tumor, probably an acoustic neuroma
Neurofibromatosis?
Peripheral neuritis of unknown cause?
Old left brachial-plexus injury

ANATOMIC DIAGNOSIS

Acoustic neuroma

PATHOLOGICAL DISCUSSION

DR. CHARLES S. KUBIK: Dr. Rose did well to concentrate on the evidence pointing to a tumor of the pontocerebellar angle. Operation disclosed an encapsulated tumor lying against the left side of the pons anterior to the cerebellum. Microscopic examination of the part removed showed it to be a neurofibroma. Considering the location one may be certain that it was a tumor of the acoustic nerve.

This establishes the check-off scheme sometimes employed to hinder defections from the ranks of organizations that fear difficulty in maintaining membership and to impose on the employer the burden that properly belongs to the organization of providing a collection agency. Under the check-off system, a member who finds membership no longer advantageous cannot quietly and without explanation cause his membership to be terminated by the simple expedient of omitting payment of dues. He must take affirmative action and resign from the organization, with danger of loss of social standing among his fellows, and he must notify his employer that his membership has been terminated, with the possible loss of esteem by his superior officers if the organization happens to be a pet scheme that they are promoting.

If Group Health Association succeeds in establishing the check-off system as a proper and lawful way of insuring the payment of the present and prospective debts of government employees, it will undoubtedly prove a boon to labor unions, finance corporations, merchants who do business on the instalment plan, landlords and others, who under the law cannot attach or garnishee the salary of an employee of the federal government but who will be able to protect themselves in advance by demanding assignments of federal salaries as securities for debts. If Group Health Association is going to have the check-off system adopted by the federal government for its benefit, there is no reason why any and every other person, whether individual or corporate, may not claim the same privilege.

Such comment is so irrelevant that it can have but little force.

Forgetting the principles relating to sickness insurance adopted by the House of Delegates of the American Medical Association in 1934, the seventh of which states that "medical service must have no connection with any cash benefits," the article comments

The association does not undertake to indemnify its members in cash, which would help the member to provide himself and his dependents, in time of sickness and in time of health, with the necessities of life, including medical service, but to indemnify him only in medical and hospital services,

And then the article resorts to the following extraordinary line of reasoning

Under the scheme proposed by Group Health Association, far greater benefits will accrue to the richer and more liberally paid employees of the Federal Home Loan Bank Board and its affiliates and of such other

government agencies as may identify themselves with the scheme than to employees of more meager resources. The scheme is so planned that the richer and more liberally paid employees are to obtain medical services at rates based on the incomes of the poorest employees. The courts have repeatedly held that the value of medical services rendered to a patient may be properly appraised in relation to his wealth, just as the value of the interests that the lawyer is called on to protect, whether interests involving the life of his client or his client's property. Under the present scheme, fees that are charged for medical services to the richer and more liberally paid employees are to be identical with those charged employees of the lowest grade, doing part time work. The richer and more highly paid and influential employees are therefore to gain the most financially by this scheme. Nothing in the certificate of incorporation or by laws assures to those lower in the ranks that they will receive the same quantity and class of medical service as that provided for their superiors.

And, in another place it is stated

Especially would quality be likely to fail in times of epidemics and of any unusual prevalence of disease, when the limited medical staff of the association would be overworked and could find no relief.

One might comment that the courts do not demand that patients voluntarily pay according to their wealth. Payments under hospital service corporations or any form of insurance policy are not appraised in relation to wealth and are not illegal. There is nothing in the certificate of incorporation that says that those of lower rank will receive poorer service. In times of epidemic it seems likely that the quality of other medical services also would fail.

There appears to be much in the attitude and substance of the article quoted that reflects a prejudice that has interfered with judgment. If the charge of illegality cannot be sustained it is useless. Too many educational and other institutions have indulged in the so-called corporate practice of medicine to make applicability of this point of law likely. The irrelevance of most of the criticism of this attack on a medical scheme which may be viewed critically by many of the profession renders it ineffectual. Had Group Health Association adhered to the principles that have successfully guided hospital service corporations, the relation of doctor to patient and patient to hos-

GROUP HEALTH ASSOCIATION, INCORPORATED

CRITICISM that reveals hostility or prejudice is often ineffective.

An article prepared by the Bureau of Legal Medicine and Legislation of the American Medical Association in the October 2 issue of the *Journal of the American Medical Association* characterizes Group Health Association, Incorporated, as "unlicensed and unregulated health insurance and corporate practice of medicine" sponsored "morally and through a contract of such a character that neither the Federal Home Loan Bank Board nor Group Health Association is willing to make it public."

The article states

Its certificate of incorporation is a feebly disguised attempt on the part of the organizers to obtain authority for the association, without liability on the part of its members, to treat its members and their dependents, through hired servants and agents of the association, for any and all manner of disease and injury, and its so-called by laws elaborate on that plan. This certainly constitutes the practice of medicine by the association, notwithstanding the fact that the association is not and cannot be licensed so to practice.

If and when Group Health Association begins to practice medicine as proposed in its certificate of incorporation and its by laws, the United States District Attorney and the corporation counsel for the District, in pursuance of the duties of their respective offices that they have sworn to perform, will be bound to take action to enforce the law.

From what has been said it is to be assumed that the attempt of the organizers of Group Health Association to incorporate is ineffective and that the members of the organization constitute only a voluntary association.

In spite of this rather extreme view taken by the representatives of the American Medical Association, Group Health Association opened on October 30. The prospectus states

The aim of this plan is to make available to Federal employees in Washington, and to their families, adequate medical care, both preventive and curative, to provide this care at moderate cost, and to place that cost on a regular, budgetable basis within the means of the group to be served. If Federal employees are typical of the general population with equivalent incomes, many do not now obtain adequate medical care, especially preventive service and care in chronic conditions, while many others incur disastrous debts each year because of sickness costs. The provision of better care should promote health and well being and reduce time lost from work because of illness. The plan should be of benefit not only to the employees and their families, but also to the Government they serve.

The form of application for membership offers the member the option of paying his dues personally or of assigning to the association so much of his salary, the payment to be made by the employer. Thus payment for the service may be made just as payments are made to most hospital service corporations. Apparently the writer in the *Journal of the American Medical Association* forgets the voluntary aspect of membership and choice of payment, for the article states

in the eighth month of gestation, because of the recurrence of painless vaginal bleeding

There was no family history of carcinoma, pulmonary tuberculosis, diabetes or nephritis. As a child, the patient had had measles and mumps. At the age of seven her tonsils and adenoids were removed. Catamenia began at twelve with a regular twenty-eight-day cycle, lasting four days. The last menstrual period began on February 1, 1937.

The antenatal course was uneventful until September 12, 1937, at which time she was admitted in the seventh month of gestation because of painless vaginal bleeding. At this time a suitable blood donor was procured. Sexual congress had immediately preceded the onset of bleeding. During her hospital stay she stained for the first two days only, and was discharged at the end of one week. The impression was that the patient had a placenta previa but because the bleeding had stopped, she was discharged to be observed in the prenatal clinic.

Following this the patient was seen in the prenatal clinic on two occasions. The blood pressure had a tendency to be high, averaging 140 systolic and 85 diastolic. The fetal heart sounds were normal. Examination of the urine revealed no albumin or casts. The total gain in weight amounted to 18 lb.

When admitted to the hospital at 9 a. m., the patient stated that she had flowed very freely early in the morning, but she was staining very moderately when she arrived. She had no abdominal pains or cramps and denied any local trauma. Examination revealed a well-developed and nourished young woman. The temperature was 98.6°F, the pulse 84, and the respirations 20. The pupils reacted to light and accommodation. The teeth were in good repair, and oral hygiene was good. The nasal passages were clear. The tonsils had been cleanly removed. The thyroid was not palpable. The heart was normal in size, the sounds were regular and clear, without murmurs. The blood pressure was 138 systolic and 80 diastolic. The lungs were normal to percussion and auscultation. The fundus of the uterus was seven fingerbreadths above the umbilicus, and the uterus was soft. The fetus was presenting by the vertex. The fetal heart sounds were not heard. Staining continued throughout the morning. At 2 p. m. she began to have mild labor pains at seven- to ten-minute intervals, and the vaginal bleeding increased. At 3 p. m. the mild labor pains continued at five- to seven-minute intervals, with a slow continuous loss of blood. A rectal examination revealed a thick uneffaced cervix, which admitted the width of one and a half fingers. The head was just above the ischial spines. In view of the findings, it was felt that the baby was dead, and

it was deemed advisable to control the bleeding and to hasten delivery from below.

Under nitrous-oxide and oxygen anesthesia, vaginal examination confirmed the rectal findings, and in addition, the edge of the placenta could be felt implanted posteriorly and low down in the lower uterine segment. The membranes were ruptured artificially, a Number 5 Voorhees's bag was inserted, and a 5-lb weight attached to the stem. A sixth of a grain of morphine sulfate was given hypodermically, and the patient was returned to the labor room not bleeding and in good condition. Four hours later the bag was expelled, and a still-born nonmacerated fetus delivered spontaneously immediately afterward. The perineum remained intact, and the secundines were expressed complete five minutes later. The total loss of blood at the delivery did not exceed 300 cc. Examination of the placenta revealed a small adherent blood clot at one margin which was in all probability the part felt low down in the lower segment, but in addition there was an old black adherent circular clot about 7 cm in diameter and 4 cm in depth in the center of the placenta. On removal of this blood clot, the typical depression in the placenta could be seen. This settled the diagnosis, namely a partially separated placenta, and explained the cause of the dead fetus. In addition, the patient had a low implantation of the placenta.

The puerperium was entirely uneventful. The uterus involuted normally. The blood pressure averaged 124 systolic and 80 diastolic. Two specimens of urine showed a trace of albumin, and a third and last specimen was entirely normal. The patient was discharged on the twelfth day in good condition.

Comment. This case from the history of painless bleeding at the onset suggested placenta previa. The soft abdomen also favored this diagnosis. The bleeding in the seventh month, at the time of the patient's first admission to the hospital, was apparently due to a slight separation of the placenta, a blood clot being formed which stopped the bleeding and allowed the pregnancy to continue until the next bleeding episode.

Conservative treatment, as was followed in this case, is indicated when the baby is dead and when there is no evidence of placental apoplexy (Couvelaire uterus).

COLDS AND WHAT TO DO FOR THEM

Most people look on a cold as a nuisance rather than an illness which should be treated. They would not miss work for such a little thing as a cold in the head, still

A Green Lights to Health broadcast given by Dr. George P. Reynolds on Wednesday, December 29 and sponsored by the Public Education Committee of the Massachusetts Medical Society and the Massachusetts Department of Public Health.

pital could have been left almost unchanged, the liabilities incident to payment of physicians' salaries and hospital fees would not have been directly incurred by the association, and the members might have had free choice of physicians and hospitals, and thus the services of all the physicians and all the hospitals of Washington, at their service. With these possibilities at hand the wisdom of the association's actions might well have been questioned effectively.

It is almost inevitable that many plans and laws concerning medical service will be presented in the next few years. The manner in which the interests of the medical profession in relation to such matters is represented is of vital importance to physicians.

PNEUMONIA PUBLICITY

A LETTER published in this issue of the *Journal* announces that the Massachusetts Department of Public Health is going before the public with information in regard to the serum treatment of pneumonia. This is an opportune time for such publicity. The pneumonia season is just beginning, and during the next few weeks more than thirty residents of Massachusetts will contract lobar pneumonia each day. More than twenty of these individuals will be ill of pneumonia of types for which serum treatment is available. Serum can save the lives of some of them and ameliorate the symptoms in a good many others.

Massachusetts was, of course, one of the first states to plan a concerted program to save the lives of those stricken with pneumonia. A recent issue of the *Commonwealth* contained the report of the five-year pneumonia program which had been carried on in Massachusetts. This pioneer work has stimulated interest in many parts of the country and at the present time nineteen states have adopted some kind of a pneumonia program and ten others are on the point of doing so.

Up to the present time very little publicity in regard to this program has been going directly to the people of the State. Most of the information has been directed to the medical profession. Because of the widespread interest in the subject, articles are beginning to appear in national peri-

odicals. Many of these are being read by laymen. For this reason it would seem to be an opportune time to place accurate facts in regard to the subject before the people of the Commonwealth.

MASSACHUSETTS MEDICAL SOCIETY

STATED MEETING OF THE COUNCIL

A stated meeting of the Council will be held in John Ware Hall, Boston Medical Library, 8 Fenway, on Wednesday, February 2, at 10.30 a. m.

Business

- 1 Call to order at 10.30 a. m.
- 2 Reading record of last meeting in abstract (published in detail in the *New England Journal of Medicine*, October 28, 1937)
- 3 Obituaries of Councilors who have died since the last meeting
- 4 Report of Auditing Committee and of Treasurer
- 5 Reports of standing committees
- 6 Reports of special committees
- 7 Appointment of new committees
- 8 Appointment of delegates
 - (a) To the House of Delegates, American Medical Association, for two years from June 1, 1938
 - (b) To the annual meetings of the five New England state medical societies in 1938
 - (c) To the Annual Congress on Medical Education and Licensure of the American Medical Association at the Palmer House, Chicago, February 14 and 15, 1938
- 9 Incidental business

Councilors are asked to sign one of the two attendance books before the meeting. The Cotting Luncheon will be served immediately after the meeting.

CASE HISTORY No 55 BLEEDING AT EIGHT MONTHS OF PREGNANCY

Mrs. P. F., a twenty-eight-year-old primigravida was readmitted to the hospital on October 8, 1937,

A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

in the eighth month of gestation, because of the recurrence of painless vaginal bleeding

There was no family history of carcinoma, pulmonary tuberculosis, diabetes or nephritis. As a child, the patient had had measles and mumps. At the age of seven her tonsils and adenoids were removed. Catamenia began at twelve with a regular twenty-eight-day cycle, lasting four days. The last menstrual period began on February 1, 1937.

The antenatal course was uneventful until September 12, 1937, at which time she was admitted in the seventh month of gestation because of painless vaginal bleeding. At this time a suitable blood donor was procured. Sexual congress had immediately preceded the onset of bleeding. During her hospital stay she stained for the first two days only, and was discharged at the end of one week. The impression was that the patient had a placenta previa but because the bleeding had stopped, she was discharged to be observed in the prenatal clinic.

Following this the patient was seen in the prenatal clinic on two occasions. The blood pressure had a tendency to be high, averaging 140 systolic and 85 diastolic. The fetal heart sounds were normal. Examination of the urine revealed no albumin or casts. The total gain in weight amounted to 18 lb.

When admitted to the hospital at 9 a. m., the patient stated that she had flowed very freely early in the morning, but she was staining very moderately when she arrived. She had no abdominal pains or cramps and denied any local trauma. Examination revealed a well-developed and nourished young woman. The temperature was 98.6°F, the pulse 84, and the respirations 20. The pupils reacted to light and accommodation. The teeth were in good repair, and oral hygiene was good. The nasal passages were clear. The tonsils had been cleanly removed. The thyroid was not palpable. The heart was normal in size, the sounds were regular and clear, without murmurs. The blood pressure was 138 systolic and 80 diastolic. The lungs were normal to percussion and auscultation. The fundus of the uterus was seven fingerbreadths above the umbilicus, and the uterus was soft. The fetus was presenting by the vertex. The fetal heart sounds were not heard. Staining continued throughout the morning. At 2 p. m. she began to have mild labor pains at seven- to ten-minute intervals, and the vaginal bleeding increased. At 3 p. m. the mild labor pains continued at five- to seven-minute intervals, with a slow continuous loss of blood. A rectal examination revealed a thick uneffaced cervix, which admitted the width of one and a half fingers. The head was just above the ischial spines. In view of the findings, it was felt that the baby was dead, and

it was deemed advisable to control the bleeding and to hasten delivery from below.

Under nitrous-oxide and oxygen anesthesia, vaginal examination confirmed the rectal findings, and in addition, the edge of the placenta could be felt implanted posteriorly and low down in the lower uterine segment. The membranes were ruptured artificially, a Number 5 Voorhees's bag was inserted, and a 5-lb weight attached to the stem. A sixth of a grain of morphine sulfate was given hypodermically, and the patient was returned to the labor room not bleeding and in good condition. Four hours later the bag was expelled, and a still-born nonmacerated fetus delivered spontaneously immediately afterward. The perineum remained intact, and the secundines were expressed complete five minutes later. The total loss of blood at the delivery did not exceed 300 cc. Examination of the placenta revealed a small adherent blood clot at one margin which was in all probability the part felt low down in the lower segment, but in addition there was an old black adherent circular clot about 7 cm in diameter and 4 cm in depth in the center of the placenta. On removal of this blood clot, the typical depression in the placenta could be seen. This settled the diagnosis, namely a partially separated placenta, and explained the cause of the dead fetus. In addition, the patient had a low implantation of the placenta.

The puerperium was entirely uneventful. The uterus involuted normally. The blood pressure averaged 124 systolic and 80 diastolic. Two specimens of urine showed a trace of albumin, and a third and last specimen was entirely normal. The patient was discharged on the twelfth day in good condition.

Comment. This case from the history of painless bleeding at the onset suggested placenta previa. The soft abdomen also favored this diagnosis. The bleeding in the seventh month, at the time of the patient's first admission to the hospital, was apparently due to a slight separation of the placenta, a blood clot being formed which stopped the bleeding and allowed the pregnancy to continue until the next bleeding episode.

Conservative treatment, as was followed in this case, is indicated when the baby is dead and when there is no evidence of placental apoplexy (Couvelaire uterus).

COLDS AND WHAT TO DO FOR THEM

Most people look on a cold as a nuisance rather than an illness which should be treated. They would not miss work for "such a little thing as a cold in the head," still

A Green Lights to Health broadcast given by Dr. George P. Reynolds on Wednesday, December 29, and sponsored by the Public Education Committee of the Massachusetts Medical Society and the Massachusetts Department of Public Health.

less would they think of giving up any fun on account of it. Yet statistics show that of all the minor ailments which make a person ill enough to have to stay away from work, the common cold is by far the most frequent. Moreover, colds—especially neglected colds—are often the forerunners of more serious illnesses, such as infections of the ear, the mastoids and the sinuses, and all too frequently bronchitis and pneumonia. So we should seriously consider the question, What should be done about a cold?

But before we can intelligently answer this we must know some rather elementary but important facts about the disease we are discussing. First of all, What is a cold? It is an infection of the upper air passages, by which we mean the nose and throat. What causes this infection? The answer is, Many different kinds of bacteria, or as they are commonly called 'germs'—tiny living organisms, so small that under a powerful microscope they look like dots or dashes, but each one alive and capable of multiplying and of destroying human tissues. They are parasites and live in the human body just as a flea is a parasite that lives on a dog. They not only damage the mucous membrane which forms the lining of the nose and throat, but they send off poisons—called toxins—which affect the whole body and make the individual who harbors them feel sick all over.

If, then, these cold germs are so powerful and so damaging, what keeps them from going right on multiplying, spreading, eating and poisoning until they have destroyed the whole body? The answer is that the human body has, at all times, certain natural powers of resistance which act as a defense against these invaders, just as nations have armies to defend them against their enemies. Every cold may be looked upon as a battle between the invading army of germs and the defending powers of the body. The germs get a foothold because they make a surprise attack when the body has only its standing army—in other words, its ordinary powers of resistance—to defend it. But the body has reserves which it can call upon, and almost at once it begins to increase and strengthen its defenses, and so, under ordinary circumstances, it is soon able to overpower the germs and kill them off. If, however, the ordinary defenses are weaker than they should be, the germs may get a strong foothold, and if the reserves are not up to standard, the invaders may spread and become so numerous and firmly entrenched that it takes a long time and a hard fought battle to eliminate them. Thus, we see that the two most important factors in defense against colds are, first, to maintain a good standing army of defense by keeping in good condition, and secondly, when the battle is on, or when the cold has started, to do everything possible to hasten the mobilization of the reserves. Every time you get run down and tired, whether it be through overwork or sitting up too late, you lower your natural powers of resistance. When you feel a cold coming on is the best possible time to treat it, because by so doing you can most effectively and quickly mobilize the necessary additional defenses and so overcome the invaders before they have become too powerful.

With this conception of colds as a struggle between infection and resistance in mind, we are now ready to consider the question, What should be done about them? We have already suggested two answers. Let me state them more clearly. First, keep in good general condition, because by so doing you make yourself less susceptible to cold infections. Secondly, as soon as you realize that the infection has set in, treat it promptly, so as to try to overcome it before it is too firmly established. The essentials

of this early treatment are three in number (1) as much rest as possible, (2) drinking larger amounts of water to promote elimination of the poisons which the germs give off and (3) a laxative, if necessary, for the same reason, but do not upset normal digestive action by taking too much or taking it too often. The next rule is to avoid, so far as possible, exposing yourself to these germs unnecessarily. We cannot live entirely isolated from our fellow men, but undoubtedly the chief source of these germs is the air passages of people who have colds, and every time we get into a crowd of people the chances are that someone in the crowd is harboring cold germs—especially at this time of year. So do not go to the movies or to other large gatherings too often during the cold season, or since I know you will go, at least realize that by so doing you are exposing yourself. A more practical bit of advice, and one that you may, perhaps, be more likely to follow, is when you know that a person has a cold, keep several feet away from him as much of the time as possible. If you must talk business with him, try to sit on the other side of the room. If your work necessitates being near him, try to avoid having him breathe directly at you. And when you have a cold, try to protect the other fellow by keeping at a distance, by coughing or sneezing into a handkerchief, and by not choosing that particular time to go to visit people, especially those who you know catch colds easily or who are delicate.

To summarize what I have said a cold is an infection of the nose and throat, it is caused by germs that live in human air passages, that destroy human tissues, and that send off poisons, the human body has always a standing army of resistance against these invaders, and reserves which can be mobilized in a few days to add to this army. The important rules regarding colds are (1) keep in good general condition, and so maintain your resistance, (2) avoid exposing yourself to colds, (3) if you catch a cold, treat it early by rest, and by elimination, (4) safeguard others against catching your cold by keeping as far as possible away from them, especially the susceptible ones.

Q Would you explain to me just how these germs come to us, how we get them into our air passages?

A. Through breathing in air that someone with a cold has recently breathed out, in other words, the cold germs are passed from one person to another through the air we breathe.

Q Can we get them from the air in an empty room in which someone with a cold was, let us say, an hour ago?

A. Conceivably, but it is very unlikely. Cold germs do not live long in the air, especially if there is sunlight and reasonably good ventilation.

Q But people do not often breathe in each others' faces, do they?

A. Much more often than we realize. In kissing, in caring for a child or a sick person or in ordinary conversation there is a great deal of breathing of secondhand air. In fact, if you watch how far cigarette smoke will travel from the smoker you will realize that you do not even have to be near a person to breathe the air that he has had in his air passages. And, of course, a cough or sneeze from a person with a cold adds force and distance to the ordinary breath, which is literally teeming with cold germs.

Q But I always thought one caught cold from sitting in a draft, or watching a football game on a cold day, or getting one's feet wet—do not such things cause colds?

A. Exposure, getting chilled or wet, and the like, all

tend to lower the resistance of the body, and if we already have the germs in our air passages or receive them at such a time, they are more likely to gain a foothold because of the lowered resistance—the weakened condition of the standing army of defense.

Q I see. But why is it that some people always seem to get colds, while others very seldom do?

A. Again it is a question of natural powers of resistance. Those who are unusually subject to colds have less than the normal defense against germs. This may be due to poor general condition, to general fatigue or to some local condition in the nose or throat which impairs the local defenses in that region.

Q You spoke of the desirability of treating a cold when one first feels its coming on. What is the best thing to do at that time?

A. First, if possible, go home and go to bed at once. Secondly, drink all the water and fruit juices you can.

Q But what if it is impossible to go to bed? If you have housework to do, or children to care for, or a job that must be done, you cannot go to bed.

A. Drink plenty of water, take things as easily as possible, get to bed early, get all the sleep you can, and try to avoid giving the cold to those with whom you come in contact.

Q My experience with small children has been that when they have colds it is almost impossible to get them to drink anything. They are fretful and restless, and just cry and say, No, whenever I try to make them take even a sip. What can you do?

A. Yes, it is often very difficult to make a sick child take fluids. Usually if you can persuade them to taste a little bit of something pleasant, they will want more. But they are so uncomfortable and often so nauseated that, as you say, they refuse the first sip, and scolding or punishment for a sick child only makes matters worse. Sometimes quiet persuasion will be effective, but one trick is always worth trying. All children like sweets, and even when they are sick will seldom refuse a lump of sugar or a small piece of simple barley candy. This tends to make them thirsty, and if they are offered a drink a few minutes later they will often take it quite readily.

Q You speak of rest as one of the most important elements in the treatment of colds. What about the theory of working off a cold by taking strenuous exercise?

A. I believe that it usually does more harm than good. When one is battling against an infection, one tires easily, and violent exercise often results in an exhaustion which greatly depletes the powers of resistance.

Q What type of medicines do you recommend for colds? Are there not antiseptics which will kill off these germs in the nose and throat?

A. There is no antiseptic that is strong enough to kill germs that is not at the same time strong enough to damage the human tissues on which they are found. Therefore, the only medicines that we can use safely are those that are mildly antiseptic and so discourage the growth of germs rather than kill them off, or those that are soothing to the mucous membranes and so help to maintain their powers of resistance. But, though these may help somewhat, and often make the patient feel more comfortable, really the most important thing to take is plenty of fluid—water, lemonade, orange juice, and so on—a little milk is all right, but too much is apt to be constipating and is therefore undesirable.

Q When are colds most contagious, and how long are they contagious?

A. They are probably most contagious at the very beginning. In the first place, the germs are then most numerous, and the body has not yet developed its powers of resistance sufficiently to begin to kill them off or weaken their strength. In the second place, the first day or two of a cold is the time when there is the most sneezing and coughing, and therefore the greatest spread of germs through the air. A cold remains contagious as long as there are any germs in the nose and throat, in other words, as long as any signs of the cold persist, but it is certainly less catching in the later stages, because there are fewer germs and those that have survived are weaker.

Q What can be done to avoid spreading colds in a family?

A. Do not breathe in each other's faces, and teach the children and the adults to cover their faces with a handkerchief when they cough or sneeze. If you have a cold and must take care of the baby, tie a handkerchief or piece of gauze over your nose and mouth and keep it there so long as you are in the room with him.

Q I shall try to remember these answers, and finally, tell me again the best way of avoiding catching cold?

A. Keep out of crowded places as much as you can during the season when colds are common. And avoid fatigue, exposure and lack of sleep—in short, anything that lowers resistance.

MISCELLANY

BULLETIN OF GENITOINFECTIONOUS DISEASES

The Massachusetts Department of Public Health, in co-operation with the United States Public Health Service, is sponsoring and distributing the new *Bulletin of Genito-Infectious Diseases* edited by the Massachusetts Society for Social Hygiene. The first issue appeared in September, 1937.

With discussion of genito-infectious diseases for the first time in history no longer suppressed by newspapers and magazines, and with the United States, under the leadership of Surgeon General Parran, engaged in a campaign for the control of gonorrhea and syphilis, every such effort is valuable and timely. Education is the mightiest weapon against these diseases, and education can come only with the freest publicity. If any slogan were necessary for this modern crusade, it might well be, "Ye shall know the truth and the truth shall make you free."

MOTOR VEHICLE DEATHS FOR 1937

Motor vehicle deaths in 128 major cities increased 7 per cent in 1937 over the previous year, according to reports recently made public by Director William L. Austin, Bureau of the Census, Department of Commerce. Deaths for 1937 totaled 9964, compared with 9308 for 1936, an increase of 656. A major part of the 1937 increase occurred during the first six months of the year. Deaths for this six month period exceeded the first six months of 1936 by more than 17 per cent. During the latter part of the year motor-vehicle deaths were not essentially higher than for the corresponding period of 1936.

Considering only those deaths in each city due to motor vehicle accidents occurring in the city, the 1937 reports show a total of 7116 deaths. This 1937 figure is an increase of 326 deaths, or 4.8 per cent, over the 6790 deaths

Hospital, Battle Creek, and, in miscellaneous institutions.' From these data, therefore, I am inclined to believe that the comparison of these cities with Boston is fair since I was also informed by the Health Department of that city that 'from a special survey' they knew of 82 deaths 'in various places.' I am, however, pleased to note that in 1936 the death rate of Boston residents, 63 per 100,000 population, was 9 per cent lower than that of the year previous, and that this decline was registered at a time when in general the tuberculosis death rate was stationary or even going up in other cities.

One of the main purposes of my survey has been to bring to the attention of those interested in tuberculosis and of the registration authorities the need of a national interchange of death certificates so that proper correction for residence can be made. Even granting the difficulty of securing a complete tracing of all the out-of-town deaths of the residents of the communities studied, it must be admitted that the survey, which has been conducted with increasing efficiency over a period of years, furnishes at the present time the only fairly close approximation to the real mortality record of the large cities of the United States.

Tuberculosis, still taking so many people in the prime of life, does seem to me to remain a sufficiently serious condition that we may forget the minor question whether the death rate is one or two points more here or there. We should, instead, concentrate on attaining, as I know the authorities in Massachusetts particularly are earnestly striving to do, a real control and eradication of the disease.

I should like to add gratefully, in disagreeing slightly with Dr Wilensky as to the completeness of my annual tuberculosis survey, that here in New York City, in our development of district health centers, we have on several instances been greatly assisted by his wide experience and wise counsel, also, that on prized occasions we have been deeply inspired by the remarkable antituberculosis work and program of the Commonwealth's Commissioner of Public Health, Dr Chadwick.

RECENT DEATH

CLARK—SIDNEY A. CLARK, M.D., of 188 Bridge Street, Northampton, died January 14. He was in his seventy third year.

A native of Northampton, he received his early education in the local schools, later attending Amherst College from which he graduated in 1888. He received his medical degree from Harvard Medical School. For many years he maintained an office in Northampton being the oldest practicing physician of that city at the time of his death.

Dr Clark was a fellow of the Massachusetts Medical Society and the American Medical Association, and held memberships in several Masonic bodies, the Northampton Lodge of Elks and the Kiwanis Club.

His widow and a daughter survive him.

REPORTS OF MEETINGS

BOSTON UNIVERSITY MEDICAL SOCIETY

A meeting of the Boston University Medical Society was held on November 29. The meeting was opened by the

presentation of a case. The patient was an 85-year-old female who had been brought into the hospital because of a very slow pulse rate. Physical examination showed a well marked generalized arteriosclerosis and bilateral cataracts. There was distention of the neck veins, and they pulsed at a very fast rate. The apex rate was 40 beats per minute. Dull sounds could be heard between the slow regular beats of the ventricles. Electrocardiographic studies were made, and by putting the exploring electrode over the region of the auricles, the P waves could be brought out more clearly. These tracings showed the patient to have auricular flutter. The patient was given atropine, and due to a paralysis of the vagus, the rate was increased to 90, but there was still complete block. Following this the patient began to have auricular fibrillation—a very unusual effect of this drug.

Dr Herrman L. Blumgart spoke on cardiac pain, beginning with a brief historical introduction of the subject. The essential characteristics of cardiac pain, its location and radiation, and the various factors which determine these symptoms were discussed. The physiologic pathology of the condition and the pathological findings in patients with cardiac pain were reviewed. The particular characteristics of cardiac pain in patients with rheumatic heart disease, coronary arteriosclerosis, cardiovascular syphilis and arrhythmia of the heart were pointed out. The importance of emotional factors was discussed. Difficulties underlying differentiation from other conditions were particularly stressed, and a brief resumé of treatment was given.

Dr Pratt discussed the paper briefly from a physiological point of view. It was brought out that the use of nitroglycerin is not a sure test for angina pectoris because it relieves many other types of pain and does not always relieve angina pectoris. It is important to use the sublingual type of nitroglycerin tablets because they dissolve more rapidly in the mouth.

COMBINED MEETING OF THE SUFFOLK DISTRICT MEDICAL SOCIETY AND THE BOSTON ORTHOPEDIC CLUB

A combined meeting of the Suffolk District Medical Society and the Boston Orthopedic Club was held on November 17 at the Boston Medical Library. Dr Brewster of the Boston Orthopedic Club presided at the meeting, which was a symposium on pain.

Dr Hallowell Davis was the first speaker of the evening and talked on the modern physiological concepts of pain. He discussed the various types of pain and pointed out that there are two kinds of nerve fibers that carry painful sensations. The first type is made up of well-myelinated nerve fibers, over which impulses travel rapidly, these fibers carry sharp pain, the type that makes one respond quickly. The other kind of nerve fibers are either very thinly myelinated or non myelinated. They carry dull aching sensations and low grade pains, which probably arise from chemical changes in the surrounding tissues. The rate of travel of the sensation over this type of fiber is much slower than that of those previously described.

Dr Chester M. Jones spoke on the diagnostic aspects of pain in the thorax and abdomen. He stressed the importance of a careful history and the necessity of eliciting the exact quality and precise location of the pain. He discussed, in particular, referred pain and defined this as pain which is set up in a viscus or on a serous surface and which is referred via the spinal cord to the corresponding somatic nerve, and thence to its segmental distribution. Referred pains are usually well localized and may be de-

scribed as dull, gnawing or burning, or as frank pain. The threshold for this type of pain, as in any type of pain, varies greatly in different people. Referred pain is superficial and may cause a localized hyperesthesia, and it may be blocked by local novocain infiltration. Dr Jones has made a special study of pain referred from the gastrointestinal tract. He studied the areas of reference of pain caused by balloons distended at different levels in the gastrointestinal tract. In general it may be said that pain referred from this system is in the midline, except for that which arises in the hepatic flexure, the splenic flexure and the cecum, and in some people, in the sigmoid. Pain referred from the esophagus is in the midline and in general at the same level as the lesion. Painful lesions of the stomach are referred to a point high in the midepigastrium. The duodenum causes pain in the middle portion of the midepigastrium and lesions of the third portion of the duodenum give referred pain low in the epigastrium. The small intestine refers its pain to the periumbilical region, and the large intestine to the midline in the hypogastrium. Pain arising in the sigmoid and rectum is often felt in the midline just above the pubic bone.

Dr Jones pointed out several unusual areas of reference and said that pain may be felt only in the back at times, or it may be referred in a segmental distribution over the course of the intercostal or lumbar nerves, on either or both sides. Lesions of the esophagus can cause pain which is typically coronary in type, or the discomfort may be localized over the seventh cervical spine. Pain felt over the seventh dorsal vertebra may occasionally be due to lesions in the stomach, and the duodenum may cause pain over the eighth and ninth dorsal vertebrae, and sometimes may give rise to a belt of pain similar to a taberc crisis. Lumbosacral pain is rarely due to lesions in the lower portion of the colon, and even a full bowel may cause this discomfort. Low sacral or coccygeal pain may come from a rectal lesion, and such lesions may refer the pain to the perineum.

Dr Jones pointed out the importance of a change in the location of pain, and cited examples of patients with duodenal ulcers, who developed similar pain in a different location signifying the development of a jejunal ulcer. Magnesium oxide may cause periumbilical pain because of its stimulation of the small intestine. The pain of mucous colitis is usually low hypogastric, as it is caused by spasm of the descending colon. Since diagnosis of lesions of the small bowel is so difficult to make, umbilical pain is of great significance and should be investigated carefully, as it almost always means trouble in the small bowel. A Meckel's diverticulum, carcinoma and partial obstruction are some of the lesions which cause this type of pain.

Dr Frank R. Ober spoke on pain in certain orthopedic conditions. In the cervical region, chronic arthritis is a common cause of pain and gives rise to considerable muscle spasm. It may be fairly well localized or may be referred to the occipital region of the head. It may cause a chronic sore throat, may cause pain beneath the shoulder blades and down the arms. Pain arising from the back may be local or referred, dull or severe, constant or intermittent, and may be affected by change of position. Arthritis in the high dorsal region may at times be confused with angina pectoris. Spinal lesions may give rise to abdominal pain, which may be contralateral. Intercostal pain is a frequent outcome of spinal disease. Pain from subacromial bursitis may be referred to the elbow, wrist or hand. Foot strain may cause pain in the sole of the foot, the ankles, knees, hips or low back. Dr Ober stressed the importance of a detailed history describing the type of pain and its exact location, and giving those

motions which aggravate it. The pain described malingering is at times difficult to diagnose clearly, usually there is no limitation of motion and the patient fails to localize the pain carefully.

Dr Elliott C. Cutler spoke on the surgical treatment of pain. This treatment is used largely for hopeless cases, distinguished between two types of pain—visceral and somatic. The somatic pain is usually sharply localized, while the visceral pain, or autonomic pain, is less localized and varies in intensity. The surgical treatment is directed at the nervous system, and it is important, before instituting this, to make sure that the cause of the pain cannot be treated. Dr Cutler first discussed the treatment of somatic pain, such as occurs in carcinoma or trifacial neuralgia. Alcohol injection is frequently used in these conditions. In the pelvis, metastatic carcinoma may give rise to severe pain, and alcohol injection, posterior nerve root section, one of two types of chordotomy may be used to relieve the pain. The posterior-nerve root section is rarely done now, chordotomy is frequently used in some clinics. The simplest type of treatment is the subarachnoid injection of 100 per cent alcohol. Since alcohol is lighter than spinal fluid, it floats up around the posterior roots on the painful side when the patient lies on the unaffected side. At the present time some clinics are using 60 per cent ethyl alcohol and 40 per cent methyl alcohol. Pain may occasionally result from this procedure, but if the patient is tipped slightly forward, the alcohol tends to bathe only posterior fibers.

The viscera are sparsely supplied with sensory nerves and are relatively insensitive. They do not feel cutting or burning, but tension causes pain. Dr Cutler discussed the autonomic nervous system which carries these sensations to the spinal cord. In 1889 the so-called sacral nerve was first resected for dysmenorrhea. This was done by severing and removing the autonomic plexus of nerves around the lower portion of the abdominal aorta, and the first 5 cm. of both iliac arteries. It is used largely for inoperable carcinoma and intractable cyclopia. In angina pectoris an attempt is made to interrupt afferent impulses. This was first done in 1916 by cutting autonomic nerves. Alcohol injection of the white rami is also done. The fibers coming from the heart are present in the first to seventh dorsal ganglia, and therefore for complete sympathetic denervation, all these ganglia must be removed or injected. None of these procedures give complete or lasting relief, they are temporary and in most cases alleviate anxiety.

Dr Walter B. Cannon discussed Dr Davis's paper and pointed out that as a rule the severity of the pain is always in proportion to its seriousness. Expectation of excitement profoundly influence the degree of pain that is felt, and when a person is excited, a lesion which would normally cause severe pain is not felt. Pain is usually worse at night and may be dispelled by hypnosis. A subjective factor is very important in interpreting Dr Smithwick's paper. Dr Jones's paper emphasized the points that he had made. Dr Osgood discussed Dr Ober's paper and called attention to the fact that pain that is referred to the abdomen. Excessive lumbar lordosis may give rise to such abdominal discomfort. Pain which is localized in the end of the thumb and in the arm may arise from a transverse process pressing on the first rib or from pressure on a cervical nerve. If some abnormally placed cervical nerve plexus. If the pressure is corrected, the arm and hand pains disappear. Dr Mixer discussed Dr Ober's paper and stressed the importance of relieving chronic pain in hopeless cases.

NOTICES

ANNOUNCEMENTS

VERNON P. WILLIAMS, M.D., announces the opening of an office at 330 Dartmouth Street, Boston.

JOSEPH L. LEWIS, M.D., announces the opening of offices at 189 Bay State Road, Boston, and at 751 Main Street, Waltham.

ANNUAL MEETING OF THE BOSTON MEDICAL LIBRARY

The annual meeting of the Boston Medical Library will be held in Sprague Hall, 8 Fenway, Tuesday afternoon, January 25, at 4:30.

Reports will be received from the Board of Trustees, the Treasurer, the Librarian and from the various committees. Three vacancies on the Board of Trustees are to be filled. Important business, having to do with co-operation between the Boston Medical Library and the Harvard Medical School Library, will be discussed.

All fellows of the Library are urged to attend.

JAMES M. FAULKNER, M.D., *Secretary*

MASSACHUSETTS PUBLIC HEALTH ASSOCIATION

The annual meeting of the Massachusetts Public Health Association will be held at the University Club, 40 Trinity Place, Boston, on Thursday, January 27. The sections will hold their annual meetings at 11:00 a.m., the luncheon meeting being held at 1:00 p.m.

SECTION MEETINGS

Board of Health Section

Discussion of Problems of Administrative Practice and Health Conservation Contests. Dr. Reginald M. Atwater, executive secretary, American Public Health Association, New York City.

Laboratory Section

The Registration and Approval of Public Health Laboratories as Carried Out in Connecticut. Dr. Friend L. Mickle, director, Bureau of Laboratories, Connecticut State Department of Health.

The Role of the Laboratory in the Control of Pneumonia. Dr. Maxwell Finland.

Child Hygiene and Public Health Nursing Section

The Responsibility of the Health Department in Community Health Education. Dr. Harold D. Chope, Director of Public Health, Newton.

Following the luncheon, Dr. Clarence L. Scamman, director, Division of Public Health, The Commonwealth Fund, New York City, will talk on "The Activities of The Commonwealth Fund."

G. DONALD BUCKNER, *Secretary*

NATIONAL SOCIAL HYGIENE DAY LECTURES

On Wednesday, February 2, designated as National Social Hygiene Day, three lectures on syphilis are being sponsored by the Boston Health Department. Each will begin at eight in the evening.

One will be given by Dr. Nels A. Nelson, director of the Division of Genitoinfectious Diseases, Massachusetts Department of Public Health, at the Whittier Street Health Unit, another by Dr. Fred J. Bailey, deputy commissioner of the Division of Communicable Diseases, Boston Health Department, at the East Boston Health Unit, Paris Street, and the third by Dr. H. F. R. Watts, commissioner of health, Boston Health Department, at the West End Health Unit, 25 Blossom Street.

Physicians are urged to make these meetings a success by calling them to the attention of interested individuals and by urging them to attend.

HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held in the Peter Bent Brigham Hospital amphitheater (Shattuck Street entrance), Tuesday, January 25, at 8:15 p.m.

PROGRAM

Presentation of cases.

Medical Investigations in Peru in 1937. Drs. Richard P. Strong, Henry Pinkerton, and David Weinman.

Medical students and physicians are cordially invited to attend.

MARSHALL N. FULTON, M.D., *Secretary*

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY, JANUARY 24

MONDAY, JANUARY 24

*8:15 p.m. New England Heart Association. Peter Bent Brigham Hospital.

TUESDAY, JANUARY 25

*9:10 a.m. Boston Dispensary. X-ray Demonstration. Dr. Alice Ettinger.

*10 a.m. 12:30 p.m. Tumor clinic. Boston Dispensary.

*8:15 p.m. Harvard Medical Society. Peter Bent Brigham Hospital amphitheater (Shattuck Street entrance).

*8:15 p.m. Boston Society of Anesthetists. Hotel Kenmore Boston.

WEDNESDAY, JANUARY 26

9:10 a.m. Boston Dispensary. Clinicopathological conference. Dr. R. C. Wadsworth. Dr. H. Houston Merritt and Dr. Arthur Berk.

*12 m. Clinicopathological conference. Children's Hospital Amphitheater.

THURSDAY, JANUARY 27

8:30-9:30 a.m. Exchange visit surgical and orthopedic staffs of the Peter Bent Brigham and Children's hospitals held this week at the Peter Bent Brigham Hospital.

*9:10 a.m. Boston Dispensary. Social Service Case Presentation. Mrs. H. B. Hooker. Miss E. Grundy.

11 a. m. Massachusetts Public Health Association University Club
40 Trinity Place Boston

FRIDAY JANUARY 23

*9-10 a. m. Boston Dispensary Some Clinical Aspects of Arthritis
Dr. Walter Bauer

*10 a. m. 12.30 p. m. Tumor clinic Boston Dispensary

SATURDAY JANUARY 29

*9-10 a. m. Boston Dispensary Hospital Case Presentation Dr.
Jacob Schloss.

*10 a. m. 12 m. Staff rounds at the Peter Bent Brigham Hospital.
Conducted by Dr. Henry A. Christian.

SUNDAY JANUARY 30

4 p. m. Illustrated public health lecture, Faulkner Hospital audi-
torium Skin Evidences of General Ill Health. Dr. E. Lawrence
Oliver

4 p. m. Free public lecture. Harvard Medical School amphitheater
of Building D Progress in Preventive Medicine. Dr. Frederick F.
Russell.

Open to the medical profession.

BOOK REVIEWS

The Collapse Therapy of Pulmonary Tuberculosis John Alexander 705 pp Springfield and Baltimore Charles C Thomas, 1937 \$15.00

This book represents not only the most recent but probably the most comprehensive volume ever written on this subject. It can be considered in no way a second edition of Alexander's monograph on *The Surgery of Pulmonary Tuberculosis*, which appeared twelve years ago. The present book is new in its concept and presentation, and is exhaustively detailed.

A departure is made in the usual sequence of presentation of material by discussing end results in the first chapter. Comparative statistics are given which amply justify and stress the importance of such therapy in pulmonary tuberculosis. The multiplicity and complexity of various available procedures, which have been designed to effect a collapse of the lung, are discussed. The matter of providing the personnel and facilities for major surgery for isolated sanatoriums is dealt with, and the qualifications for a thoracic surgeon are outlined. This chapter should be of definite interest to sanatorium superintendents, boards of trustees and public-health officials.

The value of the book has been greatly enhanced by certain fundamental chapters written by collaborators. The direct and logical presentation of pulmonary physiology in relation to collapse and the authoritative discussion of pathology by Max Pinner are alone worth the price of the book. For those actively engaged in the medical care of patients, the chapter by John Barnwell on "Pneumothorax" will be materially helpful.

From the standpoint of all readers of the book the greatest interest will focus upon the chapter dealing with the choice of operation. Here Alexander indicates how he "picks his cases." Line diagrams of 84 types of pulmonary and pleural lesions are shown, each with a suggested plan of treatment. Even though it has been pointed out that the selection of operations should not be made from the roentgenogram alone, it is quite likely that this part of the book will be used in various sanatoriums as a "thumb rule" of collapse therapy, just as physicians use an indexed prescription book to suggest drug mixtures for major-presenting symptoms. Surgeons who do not know the fundamentals of collapse therapy or the basis underlying the principles of each procedure in question should have no voice in the selection of a collapse measure. Those who do will give better advice by not matching up the patient's x-ray with a book diagram, and not being guided by a proposed schedule of treatment combinations.

Other shortcomings might be pointed out for those who might consider using the book as a "bible of collapse therapy." Thoracic surgery is a relatively young branch of surgery. Many operations are not as yet standardized. Therefore, it is unfortunate that the author passes judgment on certain procedures on purely theoretical grounds. In certain instances this has been done after specifically stating that the author has had no personal experience with a particular method. It is also regrettable that certain operations receive such scant mention. Two such procedures are pneumonolysis, or lung mobilization comitant with thoracoplasty, and extrapleural pneumonolysis with maintenance of an extrapleural pneumothorax. To the reviewer it seems that these procedures may in the future be highly regarded and take an important place in collapse therapy. In such a volume the author might well have considered a chapter on roentgenologic

problems in pulmonary collapse, because of its essential bearing on the management of such patients. In the chapter on anesthesia, nitrous oxide and oxygen has been unconvincingly proposed as the ideal for such cases. The whole anesthesia problem, one of the most vital of all, is hardly treated with its just deserts.

There are so many fine things about the book, however, that its merits far outweigh its shortcomings or debatable subject matter. It can be highly recommended to all students of pulmonary disease.

Operative Obstetrics A guide to the difficulties and complications of obstetric practice J. M. Munro Kerr, with the assistance of Donald McIntyre and D. Fyfe Anderson. Fourth edition. 847 pp. Baltimore: William Wood & Company, 1937 \$12.00

This book is an extremely thorough and detailed work by a well known obstetrician and teacher. As the title indicates, it is not a book for the student but rather for the more advanced man who has had a good basic training in normal obstetrics. The book is excellently written in simple and clear English with entire absence of verbosity. The writer puts his thoughts and opinions on paper in such a way that they are easily understood by the reader. The text is well filled with good diagrams and pictures.

It is of particular interest that this work coming from Scotland differs so little from the accepted teachings in this country. There are no important points of difference in methods of treatment from those to which we are accustomed. In certain procedures the author could find support for his opinions in many of our publications. However, the practice of injecting uroselectan into the amniotic cavity to ascertain the position of the placenta seems somewhat drastic. The writer does admit that this will start patients in labor.

The author has an excellent chapter on prenatal care. Sepsis and avoidance of vaginal examinations are well emphasized. Destructive operations on the dead fetus for the sake of the mother are fully argued. This point might well be brought more often to our attention. While showing a conservative attitude toward cesarean section, the writer feels that this is frequently the proper treatment for the elderly primipara. His enthusiasm for external version in all breech positions has a very sound basis. In vertex posterior positions he favors manual rotation whenever possible. A rather simple procedure of possible value is that of pressure on the abdominal aorta in cases of postpartum hemorrhage.

In regard to anesthesia the author admits the dangers of chloroform but at the same time states that it is the most convenient anesthetic and is safe in ordinary simple deliveries. He rather surprisingly dismisses ether because of the bronchial catarrh following its use, and states that in most large hospitals nitrous oxide and oxygen is the standard procedure. He is most enthusiastic over spinal anesthesia in cesarean section and in hard, forceps deliveries. Local infiltration with novocain is recommended for perineal repair and low forceps. The author is not enthusiastic over the use of analgesics in the first stage of labor but does admit their occasional value. Chloral hydrate and potassium bromide, and morphine and scopolamine, are his first choices.

The book can be recommended most highly to those who desire a fresh and up-to-date point of view on the obstetrician's problems.

FACTS AND ISSUES REGARDING PUBLIC MEDICAL CARE

MICHAEL M. DAVIS, PH.D.*

NEW YORK CITY

ORGANIZED medical care, supported by taxes, has long been extending in the United States. Local and state welfare officials, health officers, directors of municipal, county and state hospitals, and many non-governmental agencies including the medical and dental societies are now concerned with administering public medical care in most cities and in many counties and rural areas. How much more tax-supported medical service shall we have? The "Principles and Proposals" recently presented by over four hundred physicians have directed widespread attention to this question.

General proposals must ultimately be translated into specific plans of action. What facts are now known, what facts need to be ascertained, what issues must be faced, as a basis for plan-making? Since as regards public medical service in the United States we are not starting with a blank slate, the existing situation must be thoroughly understood before sound new plans can be evolved. The following questions are therefore important:

In what degree do the existing laws of the various states and localities and of the federal government provide a legal basis for public medical care?

What tax-supported medical services are now furnished?

What do these services now cost?

What proportion of these costs is now borne by the federal government? How much by the local and the state governments?

Who are the indigent?

Who are the medically indigent? The Committee of Physicians says: "An immediate problem is provision of adequate medical care for the medically indigent, the costs to be met from public funds (local and/or state and/or federal)."

What are the standards under which a person should or should not be eligible to receive public medical care?

What groups of the population would be furnished medical care if these principles were to be carried out?

How much would it cost to extend public medical services thus?

What would be the relation of tax supported care to the medical care furnished by private physicians and to that

furnished by non-governmental hospitals, industries and health-insurance agencies?

Legal Basis. The legal authority to furnish relief from public funds rests generally upon state laws, supplemented by the action of local units of government. Recent compilations show that there are states in which almost no systematic provision for general medical care is made, while on the other hand there are states such as New York in which ample legal authority exists for furnishing all needed medical care from public funds, not only to the legally indigent but to all persons who cannot otherwise obtain needed service.¹

General medical care for the legally indigent is furnished in widely differing degrees of completeness, or incompleteness, in different localities. It is rarely organized so as to include and co-ordinate the four needed services—in the home, in the hospital, for ambulatory patients and for preventive work. Even where the laws of a state supply ample authority to provide complete service, the extent and adequacy of care vary widely in different communities.² In general, the number of physicians, dentists and hospital beds in an area are found to be closer in proportion to the wealth of the area than to its needs.³

As to hospital care, authority for counties or cities to build and maintain general hospitals exists in many states, but only about four hundred and fifty local governments out of several thousand have exercised this power.⁴ Many other local governments, however, use tax funds to pay for care of their citizens in non-governmental general hospitals. As recent studies⁵ have shown, this policy is extending. The American Hospital Association and the American Public Welfare Association have adopted recommendations⁶ for the guidance of state and local agencies in the wise application of this policy.

The agencies concerned with furnishing medical care at the present time are largely non-governmental. About five sixths of our physicians are in private practice. Two thirds of our hospital beds for general and acute diseases are non-governmental. There are several thousand voluntary pub-

*Chairman, Committee on Research in Medical Economics.

lic health-agencies, dealing with tuberculosis, child welfare, visiting nursing and so forth. Some important business establishments, labor unions and fraternal and co-operative bodies have organized medical care for their employees or members, sometimes also for the families. A number of physicians own and operate their own hospitals or clinics. In medical research and education a large proportion of the agencies are privately maintained. The relation of public action in the medical field to existing voluntary agencies, including privately practicing physicians, is thus a question of outstanding importance.

As to federal legislation, the United States provides medical care directly only to a few special groups, such as soldiers, sailors, veterans, Indians and inmates of federal institutions. The chief federal participation in medical care is through financial aid to the states. This policy has long been established in public-health work, and the appropriations have been increased under the Social Security Act. In this large and varied country, a nationally administered system of public medical care is hardly conceivable. Most persons who consider the subject are likely to desire that the federal government continue its present policies, that is, be an assisting rather than an administrative agent.

Present Costs. The present expenditure of tax funds for medical care by local, state and national governments is about \$500,000,000 a year. This is about one sixth of the total of all annual expenditures for medical care.⁷ Of this amount, about \$100,000,000, or 20 per cent, comes from federal funds, four fifths comes from local and state funds. Furthermore, about 75 per cent is employed for hospital care, 20 per cent for public-health services and 5 per cent for home care and other services. Payment from tax funds to voluntary hospitals for the care of public charges amounts to about \$25,000,000 a year. Most of this is from local, some from state funds. In the rate of tax expenditures for medical care, excluding federal funds, there are wide differences among the states—from \$6.50 to as low as \$2.00 per capita. Within the same state even larger differences may be found between localities.⁸

Medical Care for Whom? Who are the indigent? They are those who, according to law and the policies of welfare administration, are entitled to receive the necessities of life from public funds.⁹ Who are the medically indigent? The term is used in an important way by the Committee of Physicians, but is not defined in their statement. It is apparently assumed to mean (to

quote the New York State Public Welfare Law) "persons otherwise able to maintain themselves who are unable to secure necessary medical care." The term "indigent," however, is not employed in this section of the New York law, the public authorities being simply made responsible for providing "necessary medical care" to persons as defined above. A great many people who are not receiving material relief would thus be included. The laws of many states and of the nation now recognize special groups of persons for whom certain public responsibilities are assumed, without, however, placing these persons in the legally indigent or pauper group. Examples are widows with young children, crippled or dependent children, veterans and the aged. Public-health services for tuberculosis and other diseases of public interest are also instances of tax-supported care which is supplied because a certain need exists, without involving the stigma of dependency.

Public medical service for persons who are not legally indigent has also developed substantially in hospitals and clinics. The admission of a person to a tax-supported hospital or clinic does not ordinarily carry with it the legal status of dependency, and in many communities carries little if any social stigma.

"Charity" or "Service"? How shall it be determined whether a person is medically indigent? Studies by a number of public bodies, medical societies, hospitals, clinics and other agencies¹⁰ show that inability on the part of an individual or a family to pay for medical care is a circumstance, not a status. The American Hospital Association¹¹ has issued statements for the guidance of hospitals and clinics which recognize that ability to pay for medical care must be determined by investigation of the individual case at the time care is sought, and that the essential elements to be weighed are costs as compared with family resources and responsibilities. The costs of different illnesses vary from a few dollars to many hundreds. There are diseases which may not require hospitalization but which do need expensive services for diagnosis or long periods of treatment, and which may cost as much as a hospitalized sickness.

It is apparent that the number of persons who at one time or another may be unable to pay for needed medical care depends on local standards and costs of care and on the distribution of economic resources. Those with low incomes may be continuously in that condition, and only the 10 or 15 per cent of the population with relatively large incomes are exempt from the risk of falling into it. Thus the legal status of indigency is not applicable to that large proportion of self-supporting

people who at one time or another may need medical care but are unable to pay for it, nor is the definition ordinarily associated with the word "charity" suitable for them. The phrase "unable to pay for needed medical care" is much more appropriate than "medically indigent."

Costs of Enlarged Program If certain standards of care and of costs were fixed, the existing expenditures in a given state—New York, for example—might be taken as a base and the question be asked: What would it cost if all the states were to spend as much? Roughly, the additional cost to the state and local governments outside of New York would be \$400,000,000.* This would mean approximately doubling the present tax expenditures for medical care made by all our state and local governments, except so far as federal subsidies carry part of the load. The expenditures within New York State for public medical services, however, are not considered adequate in respect to some forms of care in certain localities or in respect to all forms of care in some localities.¹² If the services were more nearly adequate than they are at present in New York State, the expenditures from tax funds would have to be substantially greater.

What would it cost if physicians were to receive reasonable remuneration for their services to all patients for whom public responsibility is assumed? No satisfactory basis for estimation exists at present, the amount required would vary widely, according to the scope of services rendered and to the methods and rates of remuneration, namely fees, full-time salaries, part-time salaries and capitation basis (so much per client per year). At the present time, some payment to physicians for general medical care in the homes of the poor is usually made, but payment to them for many other public medical services, particularly in hospitals and clinics, is supplied in but a few instances.

Sources of Support for Medical Service How are the present costs of medical care paid for? An

This statement is based on the following estimate:

	MINIMUM IN MILLIONS	MAXIMUM IN MILLIONS
Total expenditures from tax funds for medical care in the United States	500	550
New York State expenditures	\$0	
Federal expenditures	100	
	140	180
Net expenditures in states and local governments outside of New York State	3.0	370
Expenditures in states outside of New York @ \$6.50 per capita for 115 million people	745	745
Deduct	30	370
	43	33

estimate made in a recent book by the writer¹³ is as follows:

EXPENDITURES FOR MEDICAL CARE IN 1929

	FOR TOTAL POPULATION	FOR PERSONS OF MODERATE AND LOW INCOMES*
Total expenditures (donated services not included)	\$3 600 000 000	\$2 000 000 000
Expenditures from fees	2,800 000 000	1,300 000 000
Expenditures from taxation	500 000 000	450 000 000
Expenditures from insurance	170 000 000	150 000 000
Expenditures from charity	100 000 000	100 000 000

Eighty five per cent of population

An expansion of public medical services might increase the total expenditure for medical care, or might in part represent a transfer to taxation of expenditures now paid by individuals in fees. The expenditures in the last column of the preceding table might be described in another way. Self-supporting American wage earners now spend on the average 4 or 5 per cent of their incomes for medical care, but sickness falls very unevenly, so that the average is misleading. In any given year about half have small or no sickness expenditures, about a third have expenditures which run above 4 per cent (up to 8 or 10 per cent), and the remainder face still higher costs. If some present expenditures were to be transferred from fees to taxation, the result would be a lessening not only of the direct cost of sickness to wage earners but also of its uneven incidence—particularly if some tax-supported care were specially directed toward the more expensive diseases and services.

At this point, the principle of insurance as an alternative to that of taxation must be considered. In the recent statement of the Committee of Physicians, it is said: "Health insurance alone does not offer a satisfactory solution." The following facts support this statement, so far as it goes. From the economic standpoint, health insurance is a means of financing medical care, by which people pay a regular amount into a central fund (voluntary or governmental) from which the costs of sickness are met. In the United States, over two million persons now secure most or all of their medical care under voluntary health-insurance plans, and another million have joined plans which provide for hospital care only. In no country of the world does health insurance exist alone. In every European country which has health insurance, a substantial system of tax-supported medical care exists also, providing care for those persons who, because they have very small or no incomes, cannot pay contributions to a health-insurance system, and the private practice of medicine, paid for on a fee basis, also continues in these countries.¹⁴

From the financial standpoint, the following broad question of public policy is thus raised, In what proportions shall sickness costs for the mass of self-supporting persons of small means be borne

by (1) fees paid by the sick persons or their families, (2) regular assessments upon individuals, sick or well, which might be no more than these people have on the average been paying, and (3) general taxation? These are not mutually exclusive. The use to which each shall be put is a matter of degree, having regard to different social groups and also to different categories of medical care. The main point is that no program for expanding tax-supported care can proceed far without facing its relation to the principle of insurance.

The determination of sources of financial support for medical care is primarily the concern of those who bear the burden. Physicians, however, are greatly interested in the adequacy of the support and in the effects which different sources of support may exercise upon policy and upon the administration of service. From the medical standpoint, these and other medical issues equal or transcend in importance the economic questions. Among such issues are the advancement of prevention, the improvement of professional standards, the manner in which public medical care is organized and the quality of its administration.

Facts Needed An extension of public responsibility for medical care may require action by local, state and national governments, but it involves more than that. Many important agencies besides governmental ones are concerned with these matters, and not in a passive way—the medical and allied professions, industry, particularly large business establishments, most of which are interested and many of which have already been active in organizing preventive and curative work for their employees, labor unions and fraternal organizations of workers, organizations of farmers, and the co-operative societies, which in several states, particularly in rural areas, and in some cities as well, are showing active interest in the purchase of medical care. Economists and sociologists in some universities, and many social-welfare agencies, have also interested themselves in the subject.

But the focal issue is upon governmental policy in the employment of public funds. The next step in translating general proposals into working programs lies in study. The experience of foreign countries is extensive, but its application to American conditions can only be suggestive, not definitive. The large amount of experience in organized medical care in the United States has received slight collation, and very little scientific study. At the present time, an increase in public-health work and in tax-supported medical care, in hospitals and in homes, is taking place in many parts of this country, partly as an aftermath of the depression and partly under the direct and indirect stimuli of social-security legislation. In many localities the

organization of medical care under public authorities is now in a formative period, but there are a number of cities and counties in which much public medical care has been under way for years, under many different forms of organization. To aid in formulating specific policies and programs adapted to different communities, generalized studies covering large areas are now much less important than local ones. A number of careful investigations are needed in selected places. The collection of opinions about the characteristics and the quality of existing public medical care will be of little value. Field studies must be made, and some objective criteria must be applied.

Of prime importance in designing such studies will be agreement upon the criteria of appraisal. Such questions arise as these: Are there absolute criteria of scope, quality, costs and organization of service, or must criteria be relative to the needs or demands of the particular sections of the population concerned, or to the scope and character of the medical services which self-supporting persons of small means have been accustomed to secure in the same community?

Since public-health work is also extending by evolutionary process, special studies should be made of the comparative effectiveness and costs of preventive work for individuals under different systems of organization, for example, when services are performed by salaried health-department personnel or by individual physicians paid for work in their private offices. Hospitals and their outpatient departments present numerous problems by themselves, both professional and economic. Should more public funds be used for medical education and research? At the present time insufficient data are available as to the comparative expenditure for education and research from tax funds and private funds respectively. The needs for medical and hospital service in rural areas present major problems which have received all too little first-hand investigation.

Some of the most timely subjects for inquiry might be listed as follows:

The study of public services in selected communities, urban and rural, in different parts of the country, with reference to (1) scope, quality and costs of care provided, and (2) organization and co-ordination of services.

The relation of public medical care for sickness to the preventive services furnished by health departments, schools and other agencies.

The use of public funds for hospitals and clinics with special reference to (1) voluntary hospitals, (2) diagnostic and consultative services, (3) care of chronic diseases, and (4) rural areas.

The relation of public medical services in various states and communities to medical services supported by private practice, voluntary gifts or voluntary insurance.

The extent to which public funds, as compared with voluntary support, are now employed in medical education and research, and the comparative effects of each upon standards and results.

The possibilities of economic savings through the provision of adequate and co-ordinated medical care, both curative and preventive.

Estimates of need for various forms of medical care among persons who are receiving support from public funds.

Estimates of need for tax appropriations for medical care among special groups of persons—for example, the aged, or particular diseases or groups of diseases, such as cancer and chronic illness.

Effective inquiry into these subjects will require the participation of physicians with specialists in various branches of social science. Certain topics involving the qualitative elements of medical service are primarily for the physician, and his participation is always needed in designing studies and in interpreting data. But in many inquiries the primary technics of research are those in which economists, sociologists and statisticians are expert. The best development will require the disciplined thinking of medical and social scientists, followed by the participation of men of action.

These studies must be scientific, but they must not be academic. Social action in medical care is proceeding. Sickness is not postponed to await the outcome of contemplation. Nor are studies a ground for postponing action, for, as the preceding list shows, among the most significant types of study is the critical observation of current action and experimentation. A desire to lessen the suffering and economic loss from neglected sickness and to apply more fully the powers of medicine for the prevention and control of disease is daily impelling both physicians and laymen to action. The same desire leads also to the deliberate organization of experiments for working out the most effective and economical methods for accomplishing these results. Medical societies, unofficially organized groups of physicians, hospitals, co-operative societies, industrial organizations and public bodies are among the groups which have already initiated such action and experimentation. Medical service

must be judged from the point of view of the people who receive and pay for it, as well as from the standpoint of the physicians and institutions that furnish it. The participation of medical and social scientists is therefore needed in appraisal as well as in planning, and the rate and smoothness of progress will depend largely upon ungrudging co-operation between physicians and the public.

GASTRODUODENAL ULCER

Etiology, Treatment and End Results

BURRILL B. CROHN, MD *

NEW YORK CITY

THE problem of gastroduodenal or peptic ulcer is daily becoming of greater importance and interest. Originally a thorn in the side of the internist, who could neither understand its etiology nor control the permanent end results of treatment, it has involved surgeons in bitter dispute, has caused frequent compensation suits as a cause of disability, has interested insurance actuaries in its effects upon longevity and morbidity, and has become an increasing economic burden to states and their hospital systems. Bashford and Scott¹ in a study of British post-office employees have shown that peptic ulcer causes a definite loss of working efficiency. Of those so afflicted 31.6 per cent had an average annual incapacity of 30 days, 27.7 per cent from 14 to 28 days, 17.7 per cent from 7 to 14 days, and 2.3 per cent from 1 to 7 days.

Whether or not peptic ulcer is becoming more frequent, roentgenography has made its recognition easier. Growing knowledge of its clinical manifestations has brought to light many cases previously overlooked. The remark of Christian² in 1929, that four times as many cases were being treated in the wards of the Peter Bent Brigham Hospital as were formerly seen there, is significant of increasing recognition, if not of increasing incidence.

ETIOLOGY

Man is the only animal regularly subject to chronic peptic ulcer. It is plausible to link his psychic and emotional activity to the incidence of the disease. We may well ask whether the increasing incidence does not eventuate from changing economic conditions, with their resultant nervous and emotional stresses. The rise of modern industry and its problems, the bitter struggle between the classes and the workers' unprecedented political unrest may well be the sources of increase of some human diseases. The discord in the political and economic world and in family life of today must reflect itself in psychic activity and in the cerebral and autonomic nervous systems. Is it extreme to reconsider etiology from a neurogenic viewpoint?

Pathologists the world over find in autopsy statistics an incidence of approximately 10 per cent of active or healed chronic peptic ulcers. The entire alimentary tract is subject to ulcerations of un-

known origin—aphthous stomatitis, esophageal ulcer, gastric and duodenal ulcer, nonspecific ulcerative colitis, and ileitis and jejunitis as well. The lesion is always ulcerative, the variations in course and in pathology depending upon what digestive fluids serve the region affected, and upon the factors of secondary infection. In the esophagus, stomach and duodenum the acid peptic chyme predominates, in the small intestine, tryptic activity. In the terminal ileum and the bacteria-laden colon, infection soon assumes the more prominent role, though ulceration and hemorrhage may precede by months the infective colitis.

The disease occurs in greatest incidence proximal to the sphincters of the alimentary tract—before the cardia, before the pylorus, before the ileocecal sphincter, and before the rectosigmoid and anal sphincter. Two common denominators cover the entire alimentary tract—the autonomic nervous system and the digestive fluids. Function, secretion and motor activity are under the direct control of the parasympathetic and sympathetic nervous pathways, digestion proceeds under the influence of enzymatic activity. The cause of ulcer lies somewhere between the two.

Practically all the diseases mentioned occur in young people, or at least originate in youth, that most emotional period of life, and are carried over to full maturity. Just as the various kinds of insanity most commonly arise in youth, may we not at this same period expect diseases of the autonomic nervous system?

Experimentally, gastric erosions and ulcerations have been repeatedly produced by sections of the vagi (Zirni,³ van Yzeren,⁴ Ophüls⁵), by stimulation of the vagi (Keppich⁶), by extirpation of the celiac plexus (Gundelfinger⁷), and by various methods of stimulating or paralyzing the vagi or the sympathetic nerve fibers. True, the ulcers so produced in animals are not analogous to those in man, but they have occurred with sufficient frequency to demand attention, even though the results have been inconsistent. Functional derangements may well occur in the control of the autonomic nervous system over gastric secretion and motility. That such a disordered control might result in ulcer was hypothesized by von Bergmann,¹⁰ who visualized a localized ischemic spasm of the gastric or duodenal mucosa, with local resistance to peptic erosion diminished by the overexcited vagal influences upon secretion.

Presented at the annual meeting of the New Hampshire Medical Society, Manchester, May 19, 1937.

Previously presented before the Connecticut State Medical Society (September 22, 1936) and published in the *Journal of the Connecticut State Medical Society* (1:92-101, 1936).

Associate in medicine Mt. Sinai Hospital, New York City. Associate in medicine Columbia University College of Physicians and Surgeons.

It has been clearly shown that the immediate control of the autonomic nervous system rests in the diencephalon, more particularly in the hypothalamus and the cells of the tuber cinereum. Beatrice³¹ has demonstrated that stimulation of the hypothalamus increases peristalsis of the intestine and of the stomach and causes an increase of gastric secretion. Section of the vagi destroyed this effect. Kabat, Anson, Magoun and Ranson⁸ showed in cats direct inhibition of tone and peristalsis following hypothalamic stimulation, proving a direct relation between the midbrain and the sympathetic nervous system.

Carrying this reasoning a point further, it has been shown by Keller⁹ that experimental injuries to the midbrain of dogs resulted in marked hyperemia of the gastric and duodenal mucosa, even to the point of extreme congestion and outright hemorrhage, in several animals multiple erosions were produced just proximal to the pylorus. When this experiment was repeated with monkeys (Hoff and Sheehan¹⁰), mucosal erosions were created by hypothalamic injury.

Watts¹¹ has shown a definite influence of the cerebral cortex over the intestinal function. By stimulating the premotor area of the cortex, he produced intestinal rushes so that even intussusception resulted. Thus it seems that areas of the cerebral cortex may well influence the alimentary tract through the hypothalamus and the autonomic nervous system.

Most important of all are the observations of Cushing,¹² 3 cases of cerebellar tumor subjected to operation were found at autopsy to have suffered an early fatality from perforating lesions of the esophagus, stomach or duodenum. Stimulation of this hypothetic parasympathetic center was produced by intraventricular injections of pilocarpin and pituitrin, resulting in increased gastric motility and gastric hypersecretion. In the opinion of Cushing, these observations lend support to the proponents of the neurogenic theory of ulceration sponsored by Rokitsky¹³ and Virchow.¹⁴ To quote Cushing's own words:

Those favorably disposed toward the neurogenic conception of ulcer have in process of time gradually shifted the burden of responsibility from the peripheral vagus to its center in the medulla, to the midbrain, and now to the interbrain, newly recognized as a highly important, long overlooked station for negative impulses easily affected by psychic influences. So it may easily be that highly strung persons who incline to the form of nervous instability classified as parasympathetic (vagal) through emotion or repressed emotion are particularly prone to have chronic digestive disturbances with hyperacidity often leading to ulcer.

Up to this point the experimental physiologist can carry us as far as the midbrain and the cere-

bral cortex. Now step in the psychologist, the psychoanalyst and the anthropologist, combining to study the exterior stimuli and psychic traumas which, originating in the world of personal conflicts, activate the brain and the psyche, disturb the sympathetic ganglionic cord, and so react upon the physiologic function of the alimentary tract.

Eppinger and Hess¹⁵ emphasize the vagotonic individual as prone to ulcer, excitable, hypersensitive, with cold, clammy hands, spastic constipation, exaggerated reflexes, hyperacidity and vasomotor instabilities. Draper¹⁶ has added an anatomic, psychologic and pharmacologic constitutional type narrow-jawed and with high, closely fitting teeth, narrow dental arch and high cheek bones, together with a labile excitable temperament and a hypersusceptibility to drugs. Thus, too, Winkelstein¹⁷ speaks of the patient with ulcer as oversensitive to electrical stimulation of muscles, and with an exaggerated response to epinephrin and atropin.

If the ulcer "constitution" is thus hypersensitive and poorly protected from exterior stimuli, then when subjected to psychic trauma the patient reacts, not with a functional disturbance of the intestines or the stomach but with the production of ulcer. This is exactly the belief of Moschowitz,¹⁸ who has reviewed the hypothesis of the psychogenic origin of organic disease. Not alone Graves's disease but also ulcer may be the result of the interaction of psychic trauma and a susceptible nervous system. He finds the psyche of ulcer patients more or less uniform, they are highly irritable, sensitive, self-absorbed, "all-or-nothing folk." They are ambitious and aggressive, but suppress their emotions.

It is of interest to note that Rivers¹⁹ reports that of a group of physicians who were specialists, 20 per cent had ulcer. It is well known that doctors suffer very commonly from this disease. On the other hand, in the Himalayas and Japan, where the sands of life run more slowly, ulcer is an infrequent occurrence. In Negroes in the South, Rivers found only 1 possible ulcer in 200 hospital patients, and Boland²⁰ has similarly found the incidence in the Negro race half of that among Caucasians.

Alexander²¹ carries the story a step farther by finding by psychoanalysis in each ulcer case a psychic conflict between the necessity to give and the unfulfilled desire to be loved, with resultant overcompensation, of which the vomiting or constipation of ulcer may be part of an oral regressive syndrome. Thus the extreme infantile receptive cravings create a strong feeling of inferiority leading to the typical mechanism of overcompensation.

If even laboratory experiments with their exten-

sive systems of control give inconsistent results, open to doubt and criticism, how much more difficult of proof would be the establishment of the relation of psychic stimuli to organic disease?

I am very skeptical of the relation between personality and sex suppressions and psychic discords and ulcer. The individual whose past and present life is so uneventful that there are no conflict of desires and no disharmonies does not exist, to find emotional problems or minor sex repressions is only too easy, but their attribution to ulcer must in most cases be a non sequitur.

Nor must one go far afield to describe an "ulcer constitution." For every organic case there are 10 functional disturbances as seen in office practice. All such patients are hypersensitive, hyperirritable, with emotional problems and psychic restlessness. There are likely to be 9 with flatulence, aerophagia, spastic constipation or subjective distress to 1 with ulcer. The unknown factor which causes chronic indigestion and dyspepsia in one patient and ulcer in another has not yet been determined. Perhaps, as has been said by many writers, this factor is in the hypothalamus or the autonomic nervous system.

The local production of ulcer depends upon at least one constant factor—free gastric acidity. When critically analyzed by histamine test meals, all gastric ulcers exhibit free acidity, practically all duodenal ulcers show hyperacidity, and most of them show hypersecretion. A night Refuss curve taken during sleep from duodenal ulcer patients regularly shows a continuous hypersecretion of high acid titer. In reviewing the results of 600 cases of partial gastrectomy for ulcer, we have noted that where a successful postoperative anacidity obtains no recurrence ever takes place. All subsequent recurrences or anastomotic ulcers occur in cases where gastric acidity is retained.

The relation of acid to ulcer has been conclusively demonstrated experimentally. In the experiments of Mann and Williamson²² in which the bile and the pancreatic secretion were diverted to the ileum, the upper intestine thus being deprived of its normal neutralizing defense, ulcer occurred in 14 of 16 animals in the jejunal loop adjacent to the pylorus. Mann and Bollman²³ further demonstrated the progressive distal susceptibility of the small intestine. When exposed experimentally, by anastomosis, to the direct action of unneutralized peptic juice, the duodenum was least susceptible, the jejunum more so and the ileum most susceptible to the creation of ulcer by corrosive action of acid and pepsin upon an exposed segment of normally alkaline intestinal mucosa. Elman and Hartmann²⁴ produced in dogs spontaneous peptic ulcers of the duodenum by diverting the pancreatic juice and

causing its continuous external loss. A gastric ulcer was similarly produced by Hoerner.²⁵ In a personally observed case of pancreatic cyst in an adult with marsupialization, a permanent fistula developed which could not be closed. Death resulted from a perforating duodenal ulcer, the experimental conditions and observations of Elman and Hartmann thus being reproduced.

All other factors in the production of ulcer are of secondary importance or secondary to the ulcer. The gastritis described by Konjetzny²⁶ is probably the result of the ulcer rather than its cause. The whole problem of gastritis, its pathology and its clinical manifestations, is still very nebulous. The normal histology of the stomach in the various decades of life is still to be determined. That a severe suppurative gastritis or duodenitis can occasionally produce acute multiple ulcerative erosions of the stomach or duodenum is admitted, but this does not correspond to the chronic callous ulcer as seen clinically.

The bacterial hypothesis of Rosenow,²⁷ whose work has been so ably repeated by Haden,²⁸ is most striking. However, the finding of a streptococci in human ulcers does not establish their causal relation, nor are the experimentally reproduced acute fundal erosions in animals identical or even analogous with the chronic peptic ulcer of man.

Occasional cases of traumatic peptic ulcer have been noted. Direct or even indirect trauma to the epigastrium or the body may produce within twenty-four hours a bleeding ulcer of the stomach or the duodenum.

TREATMENT

That healing can take place is now beyond dispute. Time was when many skeptics believed that even in the intervals between attacks the ulcer lay open though dormant. The fact that approximately 5 per cent of autopsied cases show healed, scarred ulcers is an obvious token of their reparative ability. Roentgenologically, the progressive diminution of the size and the depth of a penetrating niche on the lesser curvature can be satisfactorily demonstrated until no lesion is seen. The average period of healing is from three to four weeks.

We have further clearly proved by studying resected specimens that ulcers heal in two or three weeks after a hemorrhage. During this waiting period after a severe melena, conservative medical treatment was followed. However, the hemorrhages, having been repeated, constituted a clear-cut indication for operation. The resected specimens showed filling of the crater with granulations, and the beginning of complete epithelial regeneration.

But ulcers are capable of repeated recurrences at the same site, frequently at stated times of the year, thus making it possible to formulate a life cycle for ulcer. Whether the recurrences appear once in three months, or once in six months, or after twenty years, their possibility is always to be borne in mind. Treatment is therefore aimed at immediate alleviation of symptoms, at healing of the defect in the stomach or duodenum and at the permanency of that result, that is, at the prevention of recurrence.

The usual conservative treatment, consisting of a modified Sippy diet, suffices for the average case. The basis of the local treatment is the use of milk, cream, eggs and cereals to neutralize the free acid of the gastric secretion, and the use of soft, easily digested foods to allay the irritability of the gastric wall. Thus also is the gastritis relieved. Frequent feeding of foods rich in protein, administered every one to two hours, with intermediate moderate doses of alkaline powders, causes a continuous neutralization of the free acid of the chyme, so that throughout the day the stomach is washed by a pabulum in which free acid has been adequately controlled. That such neutralization takes place can be proved by an indwelling Rehfuß tube during such a typical day (Crohn,²⁹ Wosika and Emery³⁰). With proper administration, free acid is absent except for occasional short intervals before feedings. The alkaline powders are a necessary adjunct, they should be given in small doses, 15 to 20 gr., so as to avoid the secondary reaction of acid production which accompanies excessive dosage, and to prevent alkali intoxication when absorbable alkalis are used.

The use of nonabsorbable alkalis such as calcium carbonate and the triple phosphates of ammonium is often advisable. They act as adequate antacids, and afford an ample substitute for sodium and magnesium salts when alkali intoxication—headaches, malaise and loss of appetite—threatens. So also the colloidal salts of aluminum, acting as adsorbents of acid, afford adequate substitutes for the soluble alkalis. Various preparations are on the market, most of them of a repulsive taste, but others in powder or suspension forms are very acceptable.

The dietary treatment should be followed strictly for four weeks, and more leniently for several succeeding months. In the latter period the diet is liberal and appetizing, including meats, puréed vegetables and cooked fruits, an adequate protein quotient being maintained, so that no patient need complain of monotony. Weight must be retained by adequate feeding, since loss in weight of over 20 per cent in ulcer cases leads to a high

mortality (33 per cent), as shown by Studley.³⁰

Ambulatory treatment suffices in the large majority of cases. In fact, the arduous necessities of today often make it imperative that a man be maintained as a functioning member of his family and of the community. Where complications exist or threaten, the course must be modified and bed rest insisted upon, otherwise the ambulatory treatment gives good results. It is better to allow a man with responsibilities and anxieties a moderate control of his affairs than to keep him in bed, fretful and restless and anxious, thus continuing the very agencies that probably activated the ulcer. The world-wide economic depression has probably not only increased the incidence of ulcer but also made more difficult a restful period of healing. Most patients could not be hospitalized if we would have them. However, intractable ulcers and the existence of complications often call for protracted bed rest. Here not only should the dietary restrictions be enforced in the strictest manner, but visitors should be excluded and sedatives more freely utilized. Since we are inclined to believe that vagus hyperactivity and cerebral overstimulation are factors in the etiology of the ulcer, sedation of the nervous system is clearly indicated. Beattie³¹ has indicated that the barbiturates have a sedative effect on the hypothalamus, their use in ulcer therapy is therefore to be encouraged.

In severe, intractable ulcers I find the milk-drip method of Winkelstein³² of great value. The continuous drip of milk at the rate of 40 drops a minute through an indwelling intragastric catheter or Levin tube maintains a constant buffer action in the gastric lumen. While the Sippy dietary method prevents free acidity only during the day, giving free play to its baneful activity during the night, the milk-drip method neutralizes it night and day. Anyone who studies the high acid secretion of a duodenal ulcer case during the night must be convinced of the efficacy of a drip treatment that combats it. Often a compromise is possible between the ambulatory day period of dieting and the nocturnal drip method. Patients may be allowed to continue at their activities, though dieting throughout the day. At night the patient is taught to insert his own Rehfuß tube and institute his own drip method.

The immediate effects of the drip method are excellent, and it is well applied to severe and intractable cases, particularly where night pain is a severe symptom. The results in a given case over a period of years, however, are not so much better as to warrant an enthusiastic and uniform employment of this rather arduous procedure. Recurrences are common with this as with all other methods. The employment of a continuous drip

of colloidal aluminum hydroxide, as advocated and practiced by Woldman and Rowland,³³ seems logical, although it offers little advantage over the milk-drip method

With other newer—or shall I call them new-fangled?—methods of ulcer treatment I have little sympathy. Mucin has been warmly advocated, most preparations are nauseating, and their results are disappointing. I doubt whether the deficit of mucin is a factor in ulcer cases (Anderson and Fogelson³⁴). The intravenous use of sodium chloride or sodium citrate is illogical, and has never gained popularity except with overzealous practitioners.

The intramuscular injection of nonspecific proteins or other chemical agencies was advocated long ago by Holler³⁵ and by Pribram,³⁶ and was reported from the Continent with some enthusiasm. The method went into desuetude, probably owing to its inadequacy, but has been revived of late in such preparations as Synodal and histidin, known to the trade as Larostidin. I have failed to find anything of value in these agencies. Reports concerning them in the literature to date are extremely guarded when given by men who value their professional reputation, and enthusiastic when coming from overzealous practitioners who evidence but little judgment. The use of histidin is based on the hypothesis of Weiss and Aron,³⁷ who observed that in Mann-Williamson dogs, histidin, an aminoacid by-product of protein digestion, was diminished in the intestinal segment subjected to experimental ulceration. They held that the parenteral injection of histidin offset the loss of aminoacid in the affected segment, and thus prevented in some cases the formation of the experimental ulcer, or encouraged its healing when formed. It does not seem reasonable to suppose that the daily injection of 5 cc of a 4 per cent solution of histidin can compensate for the extensive loss of aminoacid that results when the pancreatic and bile ducts of the dog are transplanted to the ileum. However, reports of its clinical use, as published by Bulmer,³⁸ Ratschow³⁹ and Rafsky,⁴⁰ are guardedly equivocal, while enthusiasts such as Manginelli⁴¹ successfully employed histidin in ulcer cases, gastric neuroses, angina pectoris and cholecystitis. Needless to say, controls are lacking. The relatively critical and controlled scientific observations of Sandweiss⁴² do not justify the routine employment of this injection method. The expense involved, the daily visits, the local and general reactions and the high percentage of recurrences after six months of this treatment fail to establish a case for histidin as against the more orthodox conservative dietary routine. Treatment by injection smacks more of the Continental fond-

ness for proprietary drugs, and probably redounds more to the benefit of the commercial houses that promote them than to the welfare of the patient.

RECURRENCES

To "cure" an ulcer under a given type of treatment that is based on diet and rest is an easy matter, succeeding immediately in 93 per cent of all cases (Crohn²⁰). To perpetuate that result is the problem. Recurrences are prone to follow sooner or later, usually soon. Several factors besides periodicity favor a recurrence. Excessive food or drink and disregard of dietary precautions, predicated upon a short memory for pain, are the most usual causes for recurrence. Like the obstetric patient, few persons can long remember the distressed days and painful nights of ulcer activity. People yield easily to the temptation of rich or spicy delicacies, indigestion, hyperacidity and ulcer recurrences result.

The abuse or even the moderate use of alcohol is injurious to the ulcer diathesis. Gastritis is intensified, a single orgy of drinking is often accountable for a recurrent ulcer. It is better for an ulcer patient to abstain from alcohol completely, small amounts of beer or even a weak highball in carbonated water is hardly injurious during prolonged remissions, but uncontrolled drinking and the taking of hard liquor in neat form or as a cocktail must be avoided.

The role of tobacco in ulcer is a debatable one. That tobacco, particularly in the form of cigarettes, increases gastric secretion and produces acid hypersecretion and pylorospasm has been shown experimentally and can be demonstrated in any Rehfuess test-meal experiment, it is commonly seen clinically in the catastrophes of adolescent amateur smokers. In fact, cigarette smoking can produce in a susceptible individual the picture of a pseudo ulcer, complete even to duodenal-cap deformity, resulting from smooth-muscle spasm in the presence of nicotine paralysis of the sympathetic nerve synapses. Such cases are difficult to recognize clinically and to differentiate from true ulcer, the history of the continuous overuse of cigarettes such as is commonly seen in men, and now also in women, should lead one to suspect nicotine intoxication rather than ulcer. In any ulcer case that is rebellious to treatment, suspect nicotineism. Many such cases clear up a few days after abstinence from tobacco. Cigars and pipes are less objectionable.

Smoking not only aggravates ulcer symptoms, but also causes recurrences. Scientific proof of this statement is obviously impossible since so many other factors enter into the persistence or recurrence of symptoms. I am not alone, however,

in believing that smoking is deleterious to ulcer cases, indeed, I insist upon all my ulcer patients' either giving up smoking or keeping it to a minimum

One of the commonest causes of ulcer recurrence is an upper respiratory infection mild or severe—rhinitis, sinusitis, gripe or tonsillitis. It is almost impossible to keep an ulcer patient cured in the presence of recurrent suppurative sinus attacks, chronic follicular tonsillitis or repeated head colds. Even pleurisy or pneumonia may result in a recurrence. Upper respiratory infection probably acts as an allergen to the bacteria resident in an ulcer site, rather than as a direct infecting agency. The clinical result is, however, the same. Focal infections must be eradicated where possible, this does not mean that every tonsil must be removed or every cheesy deposit regarded with alarm. But tonsils subject to recurrent inflammation, and particularly nasal septum deviations and sinus foci of suppuration, should where possible be removed.

Excessive mental or physical labor should be avoided, lest fatigue or exhaustion induce a recurrence of symptoms. Vacations and a change of atmosphere, both mental and climatologic, are beneficial, and often result in healing of the ulcer. Crises, bad news and mental anxiety often initiate recurrences.

Violent games also lead to recurrences. Handball and competitive sports should be interdicted, but golf is permissible.

COMPLICATIONS

The one complication that presents a problem in medical treatment is hemorrhage. Approximately 25 per cent of ulcer patients at one time or another suffer from gross hemorrhage, hematemesis or melena. The hemorrhage is frequently severe, alarming and threatening to life. Yet, critical as the situation appears at the moment of greatest exsanguination, it need not cause extreme alarm. In my own experience with gross hemorrhage, only 4 per cent of such emergencies have terminated fatally when conservatively handled. Since only 25 per cent of ulcer cases bleed, this gives a total mortality of hemorrhage in ulcer of less than 1 per cent, Hurst and Stewart's⁴³ estimate is 2.5 per cent of severe ulcer cases under hospital care, and Meulengracht's⁴⁴ 1 per cent. While much higher figures have been reported by other writers, among them Christiansen,⁴⁵ my experience indicates that under careful, conservative treatment the mortality is extremely low and the outlook good. Some difference of opinion exists as to whether to feed a patient during the period of actual bleeding. Hurst and Stewart⁴³ starve their patients for three days, as is

the practice at the Mayo Clinic. I have tried both feeding and non-feeding and after thorough observation am convinced that abstinence from all food is the advisable course. Very recently Meulengracht⁴⁴ has again advocated full feeding during the active hemorrhage, on the basis of neutralizing the free acidity and preventing digestion of the adherent blood clot in the open vessel or vessels. He attributes his low mortality (1 per cent) to this procedure. I still prefer three days of starvation, with the accessory use of a continuous intravenous drip of 5 per cent glucose. In this way fluid and available sugar are introduced parenterally in sufficient amounts to carry the patient over a critical period.

Opium and the barbiturates should be liberally administered so that the patient will be at complete rest and fully relaxed, mentally and physically. For a hemorrhage patient to be found awake and alert is evidence of a misdemeanor on the part of the hospital staff.

In counseling against the overuse of blood transfusions I again find myself in accord with Hurst and Stewart.⁴³ Severe reactions may ensue, causing more harm than good. With the patient well narcotized, one may await a drop of hemoglobin to 30 per cent or a fall of systolic blood pressure to below 90 mm before feeling impelled to institute a transfusion. With vigilance, skill and calmness hemorrhage cases can be handled with only an occasional mishap.

Meulengracht⁴⁴ has also recently noted an elevation of the blood urea in hemorrhage cases. This he attributes to kidney damage by the toxins through damage to the tissue. This acute azotemia in severe hemorrhage has been confirmed by Christiansen,⁴⁵ Holmgren⁴⁶ and others. Its significance and prognostic importance await further study. When anacidity is not produced, anastomotic ulcers occur in about 6 per cent of cases.

The mortality risk is much too high for the routine employment of operative procedures, recurrences are far too frequent for a prospect of lasting cure. Surgery should be restricted to carefully chosen cases, and should be employed only when protracted medical treatment has failed.

The problem of ulcer lies between a hypersensitive, irritable, often neuropathic patient, with an acid gastric factor, and his physician. The internist can "cure" the ulcer, the permanency of the result lies with the patient. Given a docile individual, mentally well disciplined, willing and able to co-operate throughout life with dietary precautions and the avoidance of nervous anxiety and excessive work, one who can take reverses and conflicts in his stride, a durable result is very likely. Again, given a patient who can prevent recurrent

infections and realizes the dangers of the overuse of alcohol and tobacco, a good prognosis is assured.

To the patient we must say, as we say to a diabetic, "Once an ulcer case, always a potential ulcer case", and so, having led him out of his ulcer crisis and guided him into the path of proper care and precaution, we leave the durability of his well-being to him.

RESULTS OF TREATMENT

The immediate results of medical treatment of ulcer cases are most satisfactory but the follow-ups are disappointing. There is no dodging the fact that most ulcers medically treated recur in time—sooner rather than later. Most of the recurrences take place within the first year (31 per cent), within one to four years approximately 50 per cent show recurrence, with symptoms. After three years only 41.2 per cent remain cured (Crohn²⁹), and after four years only 27 per cent. These figures are quoted from experience with ward cases representing the poorest class of clinical material, subject to privation and incapable, because of strained economic circumstances, of observing the proper dietary precautions and of avoiding excessive physical work and nervous anxiety. These estimates were made during the pre-depression period. Is it likely that the economic debacle has improved them? The figures of Friedenwald⁴⁷ and of Jordan⁴⁸ are more favorable because they represent private patients. But the general situation is none too hopeful.

For intractable cases—those suffering complications such as repeated hemorrhage, pyloric stenosis and perforation, and those suspected of carcinomas—surgical intervention is highly advisable, if not obligatory. When operation is indicated, partial resection is the method of choice, given a favorable subject and a skillful surgeon. By producing an anacidity, in all gastric cases and in most duodenal ulcer cases (66 per cent), recurrences are avoided. Women fare better than men, since recurrences in females after resection are most exceptional. Partial resection for ulcer is far more satisfactory than gastroenterostomy with its high percentages of anastomotic recurrent ulcers, varying from 2 to 30 per cent. While the operative mortality of resection (11 to 14 per cent) is higher than that of gastroenterostomy (2 to 8 per cent), its end result, when an anacidity is produced, is permanent cure.

DISCUSSION

DR. THOMAS M DUDLEY, Concord When Dr Crohn started to give his address, I made a list of questions to ask him, but it seems he has answered all of them in his very thorough discussion. His remarks on etiology were most interesting. I am glad that he spent so much time on that subject, because we see so many ulcer patients who have important points in their story indicating a neurogenic factor.

He spoke of hemorrhage as a complication. Just the other day I ran across a case of supposed hemorrhage from a gastric ulcer, with a history of previous ulcer and previous treatment. The patient was a man of about forty who three or four days after a massive hemorrhage developed obstruction. We found out that he had cirrhosis of the liver, and not gastric ulcer.

In speaking of the treatment of duodenal ulcers, I was particularly interested in Dr Crohn's mention of the milk drip. That is new to me. One of the most important problems in these cases, as Dr Crohn has said, is the control of the high acidity.

I should like to ask Dr Crohn for his impression of the tribasic phosphates of magnesium and calcium. We hear a good deal about their use in place of the routine Sippy powders. I have employed them a great deal in my cases and have always been pleased with the result. As Dr Crohn says, alkalosis seems to be more written about than seen. I think I have seen 1 case, due not to the powders but to the prolonged use of Citrocarbonate by a patient in attempting to treat his own case. He had a definite alkalosis, with persistent vomiting, which cleared up when the alkalosis was corrected.

DR. W J PAUL DYE, Wolfeboro I have been asked to discuss this paper from the standpoint of surgery—my own field. Dr Crohn has covered the ground so completely that there is little to add.

The recognition and incidence of gastrojejunal ulcer have apparently increased with the complexities of our modern, hectic and at times economically unstable life. All of us, whether physicians or surgeons, frequently encounter cases of this type, and are concerned in dealing with this very prevalent and vital problem.

It cannot be overemphasized that the treatment of these cases should by and large be medical and not surgical. Primary medical treatment shows most satisfactory results—up to 90 per cent of apparent cures. Fifty per cent may show recurrence because the prescribed medical regime has not been strictly followed, but can be relieved of recurrent symptoms under strictly supervised medical treatment.

Some surgical don'ts may well be mentioned. Do not consider surgical treatment of ulcer until medical measures have definitely failed to give relief. Do not perform a gastroenterostomy as the sole operation for medically unrelieved cases without pyloric obstruction. About 16 per cent of these cases will develop a gastrojejunal ulcer at the point of anastomosis, inasmuch as hyperacidity, one of the basic factors in the development and aggravation of such ulcers, is still present. Furthermore, the symptoms of the original ulcer are rarely if ever relieved by this procedure. On the other hand, there are definite indications for surgical intervention, to be carefully considered and done in selected cases only. These are as follows:

- 1 If a strict regime of medical treatment has failed to bring relief after eight weeks or longer
- 2 After repeated hemorrhages, uncontrolled by medical measures

- 3 In cases that show persistent pain, unrelieved after a reasonably long course of medical therapy
- 4 In cases that show a partial or complete pyloric obstruction, unrelieved by medical treatment.
- 5 In cases with perforation.

When surgical intervention is definitely indicated and deemed expedient, the operations of choice are resection of the ulcer, partial gastric resection, or duodenal resection. The type of operation naturally depends on the location of the ulcer and on special considerations in the given case. As Dr Crohn has pointed out, the operative mortality for resection (11 to 14 per cent) is higher than that of gastroenterostomy alone (2 to 8 per cent). Its end results when an anacidity is produced, mean a permanent cure.

DR. ANTON J CARLSON, Chicago For thirty years I have been particularly interested in the experimental side of this subject. Dr Crohn has been a very successful and conservative worker in this field. I wonder, however, whether we should be quite so dogmatic as to say that ulcers do not occur in anacidity. I feel that this problem has not been definitely solved. I believe also that present-day statistics on the prevalence of ulcers show a great many pseudo-ulcers, based essentially on pain and other symptoms, and that if the surgeons operated they would be unable to find an organic ulcer. This probably swells the statistics considerably.

The main point I want to make, however, is this. Dr Crohn devoted much attention to the nervous and emotional factors. There still remains the problem of whether the nervous factors can produce these effects. Dr Crohn knows as well as I do that many of the emotional states, instead of producing hypersecretion, produce inhibition of gastric secretion. In many emotional states the predominant effect is inhibition of gastric motility, as well as of secretion. I base this statement not on my knowledge of dogs alone. The nervous factors are there. But do they produce this lesion by interference with the motility, by spasms, or by hypersecretion?

I was sorry that Dr Crohn introduced the term 'hyperacidity'. I have never found any gastric secretion, in ulcer or otherwise, that was above the maximum of normal acidity. Hypersecretion? Yes. Hyperacidity? No. Dr Crohn may have later evidence on that point.

DR. HAROLD D LEVINE, Bristol I should like to ask Dr Crohn whether he has had any experience with the use of lobelin sulfate to control the tobacco habit, also whether alkalosis is most prone to occur in association with nephritis, and also with cases that have retention and vomiting.

DR. FRED E. CLOW, Wolfeboro I think I speak for many of the men in this State when I say that it is not always readily determined whether we are dealing with ulcer, chronic appendicitis or gall-bladder disease, judging from my own experience, it is easy to confuse these conditions. For six years I presumably had duodenal ulcer. It was left for a London doctor to discover that I had an extremely tender appendix. He prophesied that after its removal my symptoms would disappear, and I have had no trouble since then.

There is an apparent difference in the natural history of gastric ulcers in smaller communities. The patients with whom I come in contact in such localities have recurrences at far longer intervals—three and four years—than do those in larger centers. A good many in this audience know that patients as a rule do not return. They do not follow a diet, they do not carry out any plan of treatment.

much longer than it takes for them to get rid of their most troublesome symptoms

As to the complications of ulcer, I have for some years been connected with a hospital which has had over 10,000 admissions during this time, there have been 3 perforated, gastric ulcers, removed at operation, and 1 gross hemorrhage.

DR. DAVID W. PARKER, Manchester Dr. Crohn's statistics on massive hemorrhage are very fine. Apropos of this, the other day at a meeting in the Massachusetts General Hospital, Dr. Arthur Allen gave statistics on a series of cases over several years there—a substantial number—and began by saying that 33 per cent of the cases with massive hemorrhage formerly had a fatal termination. He added that he had been able to save, by a radical operation which he had developed, 11 of 13 subsequent cases. These figures are much better than those from New York which Dr. Crohn has cited. Nevertheless, most statistics on massive hemorrhage are much worse than those he has quoted.

I should like to have Dr. Crohn elucidate his statement that trauma will cause duodenal ulcer. That is an extremely important point, from the standpoint of compensation cases.

DR. JAMES W. JAMESON, Concord One of the important points in the treatment of massive hemorrhage is to see that the patient has medical treatment, and medical treatment alone, for the results of surgery are certainly not very satisfactory. As to the type of operation for recurring ulcers, gastric resection is unquestionably the best if it can be done satisfactorily, but for most surgeons, unless they have done a number of these operations, the operative mortality is prohibitive. The results from gastroenterostomy in cases of obstruction, however, seem to give very satisfactory results in a large number of cases. Often the poor results in secondary ulcers—gastrojejunal ulcers—are due to an improper operation. Not infrequently the opening into the stomach has been carried too far and too close, the technic of operation in such cases has much to do with the outcome.

The treatment of ulcer is a serious problem, and no matter what type of treatment is given there are a certain number of recurrences. As Dr. Clow has said, the patients in New Hampshire are rather difficult to treat, even after operation. It is impossible to depend on them, yet operation will be of no benefit unless the prescribed regime is followed.

DR. CROHN Hemorrhage can take place from conditions other than ulcer. The only physical examination I care to make in the case of bleeding ulcer is not concerned with the ulcer itself, because nothing is to be gained from that. There are several things that I want to know about a patient who is vomiting blood or passing blood in the stools. Has he an enlarged spleen? Such a spleen can easily produce symptoms similar to those of a bleeding gastric ulcer. One must be careful to avoid this pitfall.

One day the Pediatrics Service posted a notice for me to go to see a baby, probably with ulcer, vomiting blood. Fortunately I did not see the notice until the next day. By that time there was a purpuric rash all over the abdomen, and it was not difficult to make the diagnosis. In older people, cirrhosis of the liver will often trip one up. I saw a case in which a gastroenterostomy was performed for duodenal ulcer. Bleeding recurred, and I thought of the

spleen. This patient did not have an enlarged spleen, the blood count was normal. He was operated upon the next day, there was no jejunal ulcer, but the case later turned out to be one of cirrhosis of the liver.

Instead of soluble alkalis we often use the basic phosphates. I did not mention triple phosphates, they furnish an excellent means of treatment. For a patient suspected of alkalosis I should certainly turn either to the triple phosphates, the colloidal aluminum compounds, or some other preparation of that type.

As regards surgery for peptic ulcer cases, I imagine that, while not disputing my position, you all believe that partial resection is the proper surgical treatment. With reference to gastroenterostomy, whether the incidence of subsequent gastrojejunal ulcer is 13 per cent or 33 per cent, the operation is so unsatisfactory that its use should not be continued.

In reply to Dr. Carlson, I am convinced that anacidity precludes ulcer. I am assuming that it is a true anacidity. In that case I do not think there is the remotest possibility of ulcer.

As to pseudo-ulcers, there are a great many of them. The nicotine complex that resembles a pseudo-ulcer is the nearest thing to a true ulcer that I know of. But the symptoms will disappear immediately upon the cessation of cigarette smoking.

Of course, when I say that the diagnosis of ulcer is very important, I mean to imply that it must be scientifically exact. It is impossible to make a successful diagnosis on the basis of clinical symptoms alone.

So far as concerns the relation of nervous factors and the autonomic nervous system to the production of ulcer, I realize that this theory is open to attack. For every ulcer case with nervousness, hypersecretion, pain and distress, I see many functional cases without ulcer. That involves a constitutional factor which we cannot reduce to scientific terms. There are a great many persons who have heart burn—high strung individuals who go through life taking bicarbonate of soda and never develop an ulcer.

I know nothing about the use of lobelin sulfate for the control of the tobacco habit, nor do I know the relation of the development of alkalosis to an existing nephritis. I do know that nephritis has been closely associated with pyloric stenosis. It has been shown that there are definite changes that take place in the kidney, characterized by calcification, this work was done by the Mayo Clinic.

As to the incidence of hemorrhage and the mortality from it in ulcer cases, the statistics given here and abroad vary widely, running anywhere from 2 to 33 per cent. I can only tell you my own experience. The high figures given as to fatalities from gross hemorrhage of the stomach are exaggerations, and are based largely on cases not scientifically analyzed, or poorly treated in earlier years. In better groups, the mortality should not be greater than from 2 to 5 per cent.

My statement about trauma is, I realize, a controversial one, but there are some well authenticated cases, particularly in French books and periodicals, of people falling from great heights, striking on the buttocks, the back or the head, the trauma being immediately followed by symptoms of ulcer. I feel, as you do, that I would hate to go to court and testify, and try to hold my ground against a sharp cross-examining attorney. Yet, I believe that trauma can be a factor.

As to the gastroenterostomy for obstruction, I think that is the most extensive operation that should ever be done.

CEREBRAL ARTERIOSCLEROSIS

Vice-Presidential Address

WALDO J UPTON, M.D *

BURLINGTON, VERMONT

CEREBRAL arteriosclerosis generally accompanies old age, but senility is not necessarily a factor. Not infrequently the vessels of the brain show typical pathologic changes in the fifth decade, and rarely in the fourth. Generally all the vessels undergo these changes, but occasionally only part of them are affected, and in some cases pipestem arteries are found at autopsy where no neurologic or mental symptoms had been found during life.

For purposes of discussion, in order to emphasize the various types of disease, we must consider atheromatous changes in the vessels with or without calcification, and the hyperplasia of the arteriolar walls found in essential hypertension. No attempt is made to show that there are different diseases, but from the psychiatric standpoint the symptoms and clinical picture vary somewhat.

In both types symptoms are generally manifested over a long period, insidious and hardly noted until the condition is far advanced. These include restlessness, both physical and mental, headaches, irritability in varying degrees of intensity, noises in the ears, described as ringing or roaring, insomnia, usually manifested by broken sleep after a short period of rest, inability to concentrate, often attributed by the patient to poor memory, definitely poor memory, more particularly for recent events but also to some extent for remote ones, and various degrees of worry and depression. In the early stages a diagnosis of psychoneurosis is frequently made, but in a patient over forty who has been physically well and has previously exhibited no psychoneurotic symptoms, arteriosclerosis or some organic disease should be suspected. A thorough physical examination, including a spinal puncture when possible, may reveal nothing, but slight hypertension, early sclerotic changes in the retinal vessels or a slight impairment in kidney function suggest a vascular change and frequently reveal the true nature of the disease. As the arteriosclerosis progresses more definite symptoms develop, they may include further impairment of memory, temporary aphasia, more pronounced and more consistent irritability, vertigo, mental confusion, tics and convulsions. As hypertension becomes more pronounced, throm-

bosis and hemorrhage of the cerebral vessels result in paralysis or death. Any severe disturbance, shock, cerebral concussion or physical injury may precipitate any or all these symptoms, and may convert a slowly developing, possibly unrecognized, case into an actively progressive one. As the disease becomes more severe, some cases never go beyond the mental stage already described, but in others the patient shows mental deterioration to a marked degree. He becomes disoriented in all spheres, or develops delusions, usually of persecution, believing that he is being poisoned, his property is being stolen, his friends are spying on him, or his wife is being unfaithful. There may be marked sexual excitement, there are hallucinations, both auditory and visual, to which the patient may react violently, bowel and bladder control is lost, all the finer sensibilities are blunted so that obscenities are common, and the disease progresses to a profound dementia in which the patient lives in a vegetative state.

These later stages are very similar to those of senile dementia, but the age of onset is generally a reliable guide, provided a rational history is available. At autopsy arteriosclerotic brains show disseminated areas of softening, small and large areas of hemorrhage, and occasionally, atrophic areas—what is described as a worm-eaten appearance. In contrast, the brain of the senile dementia patient shows a more generalized atrophy, degeneration of nerve cells and neuroglia, necrosis and fatty infiltration, and in the cortex so-called senile plaques.

In our attempt to grasp the symptomatology of the disease, a brief review of the anatomy and physiology will be helpful. Lennox¹ has found that the gray matter of the brain has a high rate of oxygen consumption as compared with muscle, and that a continuous supply of oxygen is more important than a rich supply. Interruption of cerebral circulation produces a loss of consciousness in from six to eight seconds, and permanent injury to brain substance in as many minutes. It might be expected that the brain would be rich in capillaries, but Lennox found that their numbers were much less than those in muscle, however, blood leaving the brain carried much less oxygen than that leaving the face, and a little less than that leaving the extremities. Another factor to be

Presented at the annual meeting of the Vermont State Medical Society
St. Johnsbury, October 14, 1937.
Superintendent Lakeview Sanatorium, Burlington, Vermont.

considered is the result of hypertension on the dynamics of the spinal fluid. Fremont-Smith and Merritt,² in a study of 1400 cases uncomplicated by cerebral tumor, abscess, acute infection, syphilis, cerebral edema, hemorrhage, heart failure or epilepsy, found that the cerebrospinal fluid pressure was usually within normal limits regardless of either the systolic or diastolic blood pressure, except in 6 cases which showed a diastolic pressure of under 40 mm, and 3 which showed a diastolic pressure of over 160. They concluded that there was no relation between the spinal fluid pressure and the blood pressure, either systolic or diastolic. If this is so, we may assume that the neurologic and mental symptoms enumerated above are due chiefly, if not entirely, to interference with and limitation of the blood supply by the sclerosed arteries, and that, with fewer capillaries, there would be a more marked disturbance than would be the case with tissues having a richer blood supply.

If our premise is true, the problem may be considered as that of the proper treatment of the arteriosclerosis. But by the time the disease has progressed sufficiently to permit a diagnosis there have developed neurologic and mental symptoms which must be treated, and at this stage co-operation from the patient is the exception. A thorough physical examination is necessary in order to detect other conditions which can be relieved, and to assure the patient that his case is understood and that he is free of dreaded diseases such as syphilis, cancer, heart-trouble and insanity. Having dealt with such cases for forty years, I am convinced that they should all be hospitalized, and remain so for a long time. The two or three weeks' period usually recommended is seldom, if ever, of any benefit, and I have never found that returning the patient to his home after a short hospital treatment, with instructions to continue treatment there, worked satisfactorily. Hospital routine, monotonous as it seems to some, is of decided benefit.

Occupational therapy may help one case and not another. The patient who can find interest and enjoyment in work is relieved of some of his worry, with distinct improvement in his condition provided he does not become fatigued. Other patients are irritated and bewildered by the simplest tasks and attempts to interest them merely aggravate their symptoms. In such cases simple games, walking, talking and getting outdoors are better than weaving, knitting and the like, later on, occupational therapy may prove beneficial.

Static electricity and hydrotherapy give gratifying results, both physiologic and psychologic.

Sodium iodide, administered for extended periods in small doses, is the most effective and best tolerated of the iodides, despite its failure to cure the

organic lesions, it is extremely valuable. It should not, however, be used to the exclusion of rest, physiotherapy and psychotherapy.

Sedatives are to be avoided, as they are frequently cumulative in effect, on account of poor elimination, the result being staggering, falling, mental confusion and other psychotic symptoms. Hypnotics are generally needed early in the treatment, but should be used with discretion. They can in most cases be discarded when improvement has begun. Frequent change in the kind of hypnotic used gives better results than continued use of the same drug.

Under the treatment outlined above non hypertensive patients suffering from arteriosclerosis are greatly improved, many to a degree that enables them to resume their occupation, improvement usually is lasting, and many patients treated several years ago are still active. Patients with vascular changes and moderate hypertension frequently have a remission and remain comfortable, provided they are able to live in a quiet environment without undue physical exertion or mental irritation. Markedly hypertensive cases do not respond to treatment, the vascular symptoms are usually predominant, and the prognosis is unfavorable.

The following case reports illustrate three different types encountered in dealing with the disease.

CASE REPORTS

Case 1 A 60-year-old, married, white housewife, whose past history was irrelevant except for a spinal injury 15 years previously, to which the patient made a good mental adjustment, was admitted to the hospital in September, 1936, with a history of having become upset while trying to make a garden, she became confused and lost interest. She then became suspicious over a period of several months, refused to see people because they made her nervous, and was unable to carry on her usual household activities. She was taken to two institutions, but refused to stay in either. On entry it was stated that she had refused to eat for the past 24 hours, had refused all medication, had been unable to sleep, and had refused to speak. Immediately on admission she drank a glass of milk without protest, and thereafter ate regularly. She took her medicine at the prescribed times but was suspicious of it. During the first 2 weeks in the hospital she seldom spoke and was very irritable and often passively resistive, and appeared to react to auditory hallucinations, speaking in answer to imaginary voices. Later she became restless and excited, often being under such tension that she perspired freely. Improvement was gradual, and after about 6 weeks the patient lost her hallucinations, conversed freely, was less suspicious and slept without a hypnotic, although she became nervous after visits from her grandchildren and members of her immediate family. Her blood pressure was 144/88 on admission, and varied little under treatment. X-ray examination of the aorta and carotids showed calcification, although there was no calcification of the radials.

This case showed no hypertension but definite sclerotic changes in the arteries. The patient remained in the hos-

pital for 9 months, after her discharge she continued to make a satisfactory readjustment at home. Here is an excellent example of the results achieved through adequate treatment in an institution for an extended period, 6 weeks having elapsed before there was definite improvement.

Case 2 A 61 year-old, well nourished female had taught school for 25 years, she had had meningitis at the age of 21, but made a good recovery, for at least a year previous to the onset of neurologic symptoms she had had high blood pressure. At the onset she complained of headache and inability to concentrate. The blood pressure at that time was 220/110. The patient was unable to continue teaching and went to a quiet place in the country, where she was treated for hypertension for 3 months. However, her symptoms became progressively worse, she became depressed and thought that she had lost all her savings, she had rosacea on the face and nose, and thought this was an infection by which she might infect others. She refused to eat as she could not pay for her food, and did not use her handkerchief as she could not afford to have it washed. She was very restless and nervous, and insomnia and constipation were quite persistent. On admission the blood pressure was 206/114, the heart action was regular, without murmurs. The radials were sclerosed, an electrocardiogram showed mild deviation of the axis. The face was flushed and there was rosacea over the face and nose. The patient's speech was retarded by inability to concentrate quickly and by obscuraton. She was very apprehensive, persistently asking whether it would be all right to carry on her ordinary routine. The vertigo was troublesome, and the headaches were very severe, occurring during either the day or night. The patient complained of blur ring when she attempted to read. She was depressed, and was worried because she could not pay for her care, did not eat unless urged, and thought that her presence was objectionable to other patients. Her insomnia was aggravated by her persistently getting out of bed to look for persons that she thought were about the building, apparently reacting to auditory hallucinations (which she did not admit). This condition continued for 18 days, when it began to improve. The blood pressure had dropped to 180/104. The patient slept fairly well without a hypnotic, and was not so depressed as previously. From that time on, improvement was steady and fairly rapid. 6 weeks after admission the blood pressure was 170/100, there were no headaches

vertigo or obscuraton, and vision had improved. She conversed freely without retardation, and was able to concentrate readily. Restlessness and depression were still present in a mild degree, but the patient regained a fair measure of confidence. She came from outside the State, and for financial reasons was at this time transferred to a public institution in her home state, where she is said to be making a very satisfactory readjustment.

The history and symptoms of this case are fairly typical. Quite frequently, as here, the disease has become well advanced before a physician is consulted.

Case 3 A 46-year-old railroad engineer was referred for treatment for high blood pressure with some mental disturbance, he could not be controlled outside an institution. His past history was essentially negative. He had been without symptoms up until a year before, when he had been troubled by headaches, which were traced to hypertension and responded to treatment. He developed some difficulty while at work, could not make out his train reports or understand his orders, and could not remember things from day to day. He then noted vertigo and severe headaches, occasional pains in his left chest, nervousness, and inability to concentrate, and had to stop work. On admission he was gloomy and apprehensive. His memory was poor, he complained of insomnia, was irritable and unco-operative, would not stay in bed and was very restless and irresponsible. The blood pressure was 195/120, and previous to entry had been running persistently over 200 regardless of treatment. An electrocardiogram showed coronary changes consistent with sclerotic changes in the coronary arteries. There was a systolic murmur, but no enlargement of the heart. The serologic tests were negative, as were urine and blood examinations. The patient was given hydrotherapy, nitroglycerin, theobromine and iodides, but his blood pressure did not go below 195, he went home after 2 weeks unimproved, soon developed a psychosis, and was committed to the state hospital.

This case is an excellent example of the more rapid type of deterioration which gives a poor prognosis.

311 North Avenue.

CARCINOMA OF THE COLON

A Study of Seventy Cases

DONALD S. ADAMS, M.D. *

WORCESTER

THIS series comprises all cases of cancer of the large bowel, but not including the rectum, admitted to the Memorial Hospital in Worcester from 1923 to 1934, a total of 70. The patients were observed and treated by eight surgeons and two internists.

The youngest patient was a female of twenty-four, and the oldest a male of eighty-three. There were 2 cases in the second decade of life, 6 in the third, 10 in the fourth, 12 in the fifth, 30 in the sixth (the maximum), and a drop to 6 and 4 cases in the seventh and eighth, respectively. Gordon-Watson¹ in his series of 75 cases found only 2 patients who were under thirty. Before the second decade the incidence is uncommon, although Ewing² cites cancer of both the cecum and the sigmoid at twelve. Even in the newborn and in infants it has been recorded. Although the disease is commonest in the fifth and sixth decades of life, we should not overlook its possible occurrence at any age.

The matter of sex incidence invokes considerable discussion in the literature. In our own series there are 45 females to 25 males, a ratio of nearly 2:1. Ewing,² quoting German sources, finds 40 per cent of a large series to be males but Karsner and Clark³ report the male more frequently affected, and Rankin⁴ notes the opposite of our series, or 2 males to 1 female.

In considering the site of cancer of the colon it is interesting to note first the intestinal tract as a whole. Ewing,² quoting Nothnagel's 344 cases coming to autopsy, reports 164 occurring in the colon, 162 in the rectum, 7 in the duodenum and 11 in the ileum. Lubarsch⁵ in 1608 cases found 664 in the colon, 846 in the rectum, 69 in the duodenum, 22 in the ileum and 7 in the appendix. It is generally considered that 15 per cent of all cancers in human beings affect the large bowel and that these are equally divided between the colon and rectum.

The areas affected in the colon in order of their frequency, as reported by Karsner and Clark,³ are first the sigmoid, next the transverse colon, and last the splenic flexure. In our series the sigmoid came first with 38 per cent, the cecum next with

17 per cent, then the hepatic flexure with 13 per cent and the remainder were almost equally divided, in the other areas of the colon, the ascending portion of the colon being least affected, numbering 6 per cent. The lesion was in the right half of the colon in 36 per cent, in the transverse portion in 9 per cent and in the left half in 55 per cent.

In comparing our figures with those from two other groups, as listed in Table 1, three points in common arise. They all agree, first, on the preponderance of sigmoid cases, secondly, on the almost identical figures in terms of percentage as regards the sigmoid, and thirdly, on the greater proportion of left-sided involvement.

Table 1 Site of Colon Cancer

	KAUFFMANN ⁶	KARSNER AND CLARK ³	MEMORIAL HOSPITAL
Cecum	19.4	13.5	17
Ascending colon	7.5	17.3	6
Hepatic flexure	7.5	5.8	13
Transverse colon	11.6	17.3	9
Splenic flexure	10.3	7.7	9
Descending colon	5.3	—	5
Sigmoid	38.4	38.5	38
Right half of colon	34.1	36.5	36
Transverse colon	11.6	17.3	9
Left half of colon	54.1	46.2	55

It is generally conceded that the etiology of this disease is unknown, and our cases bear out this conclusion. Yet the literature advances numerous possible factors, such as chronic irritation arising from hard feces, or from colitis and amebic dysentery. Mention is also made of certain vitamin deficiencies, and heredity. We know that polyps in the large bowel may have a tendency to malignant change. Karsner and Clark³ estimated that 40 per cent of all cancers in this region arise from polyps. Nystrom, quoted by Dixon,⁷ goes farther, and considers that 63 per cent of cancer in this region arises from polyps.

Steindl⁸ notes that 22 per cent of a series of bowel cancers were inoperable, probably because of diagnostic errors which resulted in delayed treatment. In our group the outstanding mistake before hospital admission was treatment for what was thought to be constipation and hemorrhoids. After the cases had reached our hands, cancer of the right half of the colon was confused with both gall-bladder disease and appendicitis, also, operations were performed for supposed disease of the pelvic adnexa, which proved to be left-sided.

Read before the annual meeting of the New England Surgical Society, Providence, Rhode Island, October 2, 1937.

Surgeon to Memorial Hospital, Worcester, Mass.

large-bowel cancer With a more careful study of the history and a barium enema, the preoperative diagnoses in these cases would probably have been changed It should, however, be borne in mind that occasional cases of cancer cannot be diagnosed with certainty It is in this type of case that exploratory incision is indicated

Dixon⁷ and his colleagues note that the greatest number of errors in diagnosis of cancer on the right side occur in patients with unexplained secondary anemia, pernicious anemia, peptic ulcer, gall-bladder disease or appendicitis with abscess, on the left side, appendicitis, colitis, spastic colon and disease of the pelvic adnexa cause errors in diagnosis He quotes Rosser, who observed a similarity between cancer of the cecum and the ascending colon and appendicitis, but points out that patients with new growth show weakness and anemia but no temperature Bloodgood⁹ warns that transverse-colon cancer in particular may simulate gastric disease, even to the point of loss of hydrochloric acid

In our cases the following complaints were listed: complete inability to move the bowels, a change in bowel habits to the point of unusual constipation, pain, gas, with and without unusual distention, nausea, vomiting, bleeding from the bowel, weakness, diarrhea, a persistent tender localized area in the abdomen and indigestion In addition, patients stated that they could feel a mass within the abdomen, which was verified in each instance. In 36 per cent only a single complaint was made, whereas in 64 per cent there were two or more from the list just given

The outstanding symptom was pain In only 2 instances in this series was it absent, both cases being partially obstructed by growths in the left lower colon This pain varied from a dull, gnawing sensation, usually near the region affected, to the generalized paroxysmal type caused by obstruction The former, associated with edema and inflammatory changes about the lesion, caused its local effect by direct pressure on surrounding parts The right half of the colon is more subject to these changes than is the left, where partial or complete occlusion of the bowel lumen by the new growth is the direct cause of the pain

Changes in bowel habits were next to pain in frequency Eighty-five per cent of the patients in this series showed constipation in some form, 27 per cent noting it as an outstanding symptom, which came on gradually, the bowels having been regular There was a small group who had no constipation, and in whom there was no apparent need for enemas or cathartics Of this group, 4 were left-sided cases with annular growths Apparently the patients were operated on when the bowel lumens were still sufficiently patent

It is of interest to note the duration of these symptoms before hospitalization Our series showed an average of eighteen months as compared with one year reported by Rankin,⁴ and eight months reported by White.¹⁰ The cases where the left side of the colon was involved showed longer preoperative periods than did the right-sided cases. Our average is influenced by the inclusion of the case of an elderly man with an annular growth in the splenic flexure, who voluntarily stated that his first symptom of discomfort and a feeling of something wrong under the left costal margin antedated operation by fourteen years

Sixty of our 70 cases, or 86 per cent, received some form of operative treatment. Of the 10 unoperated patients 2 left the hospital for treatment elsewhere, the other 8 were either in such poor condition that operation was not attempted, or died before anything could be done. The diagnoses were established by clinical means, by postmortem examination or by operative findings at hospitals to which the patients were transferred

The 60 cases operated upon were handled in five different ways Fifteen were treated by simple colostomy This procedure was used either as a palliative measure to relieve obstruction in feeble patients and in those obviously suffering from metastases, or as a method of bowel decompression prior to a proposed resection The operation has its place, and it was surprising to find that a number of these patients obtained relief and lived for some time.

Eight patients received some form of sidetracking around the growth This is a cleaner procedure than simple colostomy, and was chosen because of extension of the new growth and a desire to overcome the obstruction without an external colostomy

Nine patients were explored without an attempt to treat the growth These operations were done when perforation of the lesion had taken place, or where the cancer was too far advanced for either colostomy or sidetracking Nothing was accomplished in any of this group

One patient had a simple excision of an early growth of the cecum Here a subtotal hysterectomy was followed by a routine appendectomy The growth was discovered and removed

Twenty-seven patients were treated by resection of the affected bowel Of these, 26 per cent had some form of bowel decompression before or during the operation Resection with ample margins is the procedure of choice The matter of a preliminary ileocolostomy or cecostomy is open to debate. Its use had a bearing on our mortality table, however Being in favor of bowel decompression, I was glad to find that Rankin⁴ recommends its use rather than the one-stage method He uses a

preliminary end-to-side ileocolostomy for right-sided growths, and a cecostomy for left-sided ones Rankin also quotes Whipple, whose summary of the value of preliminary bowel decompression is most excellent "It allows proper cleansing of colon before resection Puts the anastomosed parts at rest until healing is complete Increases patients' comfort by eliminating ineffectual peristalsis It eliminates the use of enemas and irrigations during period of repair Its value is not only with complete obstruction but partial as well" Another well-known argument in its favor is the marked recession in size of the inflammatory reaction about the obstruction, which simplifies the resection

The Mikulicz procedure was not employed in this series Although when applicable it offers a satisfactory means of removing the new growth and re-establishing the continuity of the bowel, it is often followed by the surface implantation of cancer cells

Mortality in our series is considered in two groups, the operated and the unoperated cases The operative mortality, as shown in Table 2, was 28

Table 2 Immediate Mortality in Operated Cases

NO OF CASES	OPERATION	OPERATIVE MORTALITY	
		No Deaths	Per Cent
15	Simple colostomy	5	33
8	Sidetracking	0	—
9	Simple exploration	4	44
1	Simple excision	0	—
27	Bowel resection	8	30
60		17	28

per cent Of the 10 unoperated cases 6 patients died in the hospital These were in a moribund state on admission The 4 who left the hospital alive either desired transfer elsewhere for operation or went home to die after refusing treatment

In this series, adenocarcinoma was reported in all cases Metastases from the original lesion were found to extend locally, to regional lymph nodes, and to distant parts No bony involvement was noted The liver was the organ most commonly involved One patient had, in addition, lung and brain extension Clogg¹¹ describes the ovaries as occasional points of invasion In keeping with this, 1 patient in our series had a satisfactory resection of the transverse colon but returned in two years with an involvement of one ovary A year later the other ovary was affected with a fatal termination

Of the 23 hospital deaths, 10 came to autopsy, the sigmoid was the predominating site in 8, the cecum in 1 and the descending colon in 1 Of these 10 patients, 3 who had had resections of the sigmoid or the descending colon died through failure of the sutures to hold, with resultant peritonitis The disappointing fact here was that no

metastases were found and that the lesions had been excised with good margins Three autopsied patients who had colostomies died from heart, kidney, or lung complications At autopsy these presented local and general extension Three others were not operated on, of these, 1 died from cardiac disease and would otherwise have had a good prognosis, as no metastases were found, 1 had an unrecognized sigmoidal growth with perforation and local extension, in the third, the cecum, liver, lungs and brain were involved The tenth autopsied patient had an exploratory incision with an attempt at peritoneal drainage, the findings were perforation of a sigmoidal growth with general peritonitis, and localized metastases The striking factor in these postmortem examinations was the large percentage—70 per cent—where metastases either did not exist or were well localized It was also noted that the older the patient the more localized was the cancer

The end results in the patients who left the hospital alive but subsequently died are listed in Table 3

Table 3 Average Survival of the Cases Which Died after Discharge from the Hospital

NO OF CASES	OPERATION	AVERAGE LIFE AFTER LEAVING HOSPITAL
4	None	6 mo.
10	Simple colostomy	10
8	Sidetracking	15
5	Simple exploration	4
13	Bowel resection	2 yr

Seven patients are alive and well today Further data concerning them are given in Table 4

Table 4 Data on Surviving Cases

DIAGNOSIS	OPERATION	LENGTH OF LIFE SINCE LEAVING HOSPITAL
Cancer of sigmoid (Grade I)	Resection	6 yr
(Grade III)		3
cecum (Grade II)	Local excision	7
(Grade II)		10
ascending colon (Grade IV)	Resection	8
splenic flexure (Grade II)		3
(Grade II)		3

In conclusion it should be emphasized that to get the best results in carcinoma of the colon as in other forms of cancer, early diagnosis and treatment are essential To this end, not only the surgical profession but the public must become, as Bloodgood has expressed it, "cancer conscious" This necessitates placing the facts squarely before the public The family physician should be reached both by word of mouth and by articles in surgical periodicals The medical student and the house officer must be properly instructed in the taking of histories and the making of examinations in cases where there is a derangement of the intes-

unal tract. Finally, the surgeon must not only be able to operate on these cases intelligently, but must share in the training of the house officer and in the latter's diagnostic responsibility. With our present-day knowledge, few cases of large bowel cancer should be overlooked.

I am indebted to Dr. James P. Beck, pathologist of the Memorial Hospital, for the checking of old sections and the grading of tumors.

DISCUSSION

DR. EDWARD L. YOUNG, JR., Boston. With cancer producing such an enormous mortality every year, Dr. Adams's subject is a highly pertinent one, particularly as in cancer of the large bowel, given an early diagnosis and competent treatment, there is such a good prognosis.

Dr. Adams did not mention one thing that I have particularly noticed, that is the slight show of blood before other symptoms, with or without a change in the normal bowel habits. This is often the first symptom to be observed, and should be followed by immediate and adequate study, particularly repeated guaiac tests and barium enemas, done by a competent roentgenologist. I would rather send a patient to a roentgenologist and have him report that there is nothing there than to wait an unnecessarily long time.

When the diagnosis is made, preoperative treatment is very important. First, the patient must be prepared mentally, and should spend several days in the hospital before operation. He should be told that in all probability there will have to be two operations. The preoperative treatment is the restoration of the chemical and water balances, and also the local preparation of the bowel. The ability to complete this preparation satisfactorily, and the surgeon's experience and ability, will determine whether in a given case he can do a one-stage operation to advantage. That must be so where obstruction is insufficient to prevent adequate bowel preparation, yet in nearly all cases we may say that a two-stage operation gives a better prognosis than a one-stage operation. The cases which Dr. Allen has recently reported from the Massachusetts General Hospital bear this out very well.

There is also the question of preoperative peritoneal stimulation. I still believe that it is worth while as a means of decreasing the risk of peritonitis.

As to the type of operation, in my hands aseptic anastomosis gives the best results. For two years I have asked the pathologist to tell me if my suture material cultured at operation should fail to develop bacteria. I have not a single report of the kind. I can put catgut around an ap-

pendix stump, culture the remnant and have it reported "No growth." I cannot do this in an anastomosis of the large bowel. In other words, I doubt whether aseptic anastomosis is anything but a relative term, nevertheless, I believe this operation in some form gives a better opportunity for a clean healing than the other methods. I prefer clamps to the Kerr basting thread method, as giving better control of the bowel and carrying less danger of an obstructing diaphragm forming within the lumen.

It is essential that all cases successfully operated on shall have a regular postoperative check up. The percentage of carcinomas of the large bowel arising from polyps is high (some observers have even put it at 100 per cent). Polyps of the large bowel are so likely to be multiple that even though the roentgenologist before operation says that there is only one growth, and the surgeon on examining the large bowel at operation can find no others, there may be more of them. A secondary growth may start, and the patient may have as good a chance of cure on the second operation as he had on the first. For these reasons I consider routine postoperative check ups essential.

DR. CHARLES L. LARKIN, Waterbury, Connecticut. Dr. Adams, and Dr. Young have both stressed two requirements for the proper treatment of carcinoma of the colon. The first is that such cases must be seen in an early stage if better results are to be obtained than those which now prevail. The second is that the surgeon must be skilled in this branch of surgery. Neither of these requirements seems unreasonable, but I doubt whether the first will ever be accomplished, and certainly the second cannot be attained in communities of one hundred thousand inhabitants or less until the present medical and surgical educational facilities are augmented by intensive postgraduate study.

The only way in which early cancer of the colon will ever be discovered lies in compelling every adult above the age of thirty-five to submit to a thorough annual physical examination by a competent physician, and a routine examination of the whole gastrointestinal tract by a competent radiologist. This is of course impossible.

In Connecticut the State Tumor Committee tried to enlist the physicians of the state in a concerted effort to influence their patients to have annual physical examinations. Every doctor in the state was approached, and it was proposed that they should send out to every patient, above thirty-five, cards that read something as follows:

My Dear Mr. [or Mrs.]

The Connecticut State Medical Society recommends a yearly complete physical examination by a competent physician or surgeon as the best means of preserving health. I am in agreement with this policy and suggest that you call at my office on _____ at _____ for a check up.

If the above date is not convenient for you, please notify my office.

M.D.

The committee failed absolutely to obtain the co-operation of the doctors.

This year the committee is trying to educate the public as to the cancer menace, and to urge everyone to submit to his physician once a year for examination. I do not feel confident, however, even if people do so, that our purpose—that is, the early diagnosis of cancer—will be accomplished. Certainly so far as early cancer of the large bowel is concerned we are doomed to failure, because there are no recognizable symptoms. When such a cancer bleeds it is no longer an early one. When it causes pain it is no longer an early one. When it gives symptoms of

obstruction or even partial obstruction it is no longer an early one.

Another reason why we are unlikely to discover early cancer of the large bowel is that the average physician is too busy taking care of minor ailments to have his patient strip, to look into every orifice, to examine all the excretions, and to do everything necessary in a complete physical examination. Such examinations take time, and the general practitioner, his office filled with patients each representing a small remittance, cannot afford to spend an hour on one patient and find that the others have walked out of his office.

In a city the size of Boston it may be easy for a patient suffering from cancer of the large bowel to find a surgeon skilled in this field, but in the smaller communities he can rarely do so. In Boston and New York there has been a tendency to segregate these cases in one or two hospitals, and some surgeons, such as the late Dr. Jones, have become skilled in handling them. These men have taught other surgeons and interns in their hospitals the necessary technique, so that today the surgeons in such hospitals as the Massachusetts General and Pondville are obtaining results far superior to those achieved in the smaller hospitals. Most of us surgeons in the latter have never received training in this special line. I myself was an intern in one of the best general surgical hospitals in this country, — St. Luke's in New York, — and I do not remember seeing one abdominoperineal resection of a cancer of the rectum or sigmoid. Since starting practice in Waterbury, Connecticut, a city of 100,000 people, I have rarely seen a cancer of the colon.

At the Waterbury Hospital during the last five years only 19 cases were seen. This is a hospital of 300 beds, and the 19 cases were divided among six surgeons. It can be readily seen that no one of us has handled enough cases to become skilled in this field, and we never shall be skilled unless we are given the opportunity to take a postgraduate course at one of the larger cancer clinics. Surgeons who are connected with larger cancer hospitals would make an outstanding contribution if they were to give such a course once a year to young surgeons on the staffs of small hospitals. It will then be an easy matter to allocate all cancers of the colon to these men, and the results obtained at the smaller hospitals will then compare more favorably with those obtained at the larger institutions. The medical schools at Yale and Harvard and elsewhere in New England are failing dismally in their duties when they neglect to provide for the proper postgraduate education of practicing surgeons in this section.

DR. FRANK H. LAHEY, Boston. We have said before, and everyone agrees, that we must interest ourselves seriously in this problem of carcinoma of the colon and rectum, particularly because it is such a favorable lesion for treatment. We have done 725 operations on patients with carcinomas of the colon and rectum, of which 46 per cent were in the colon. The end results show that 47 per cent of the latter patients are alive and well and without recurrence more than five years after operation, and that 42 per cent of the patients with carcinoma of the rectum are alive and well without recurrence, that is, those patients who had the radical operations. Again I call your attention to the fact that the treatment of this lesion is very favorable, it is one of the most hopeful situations for cancer with which we deal, and it is, therefore, worth while to interest ourselves seriously in it, and to convince our patients that carcinoma in this location is far from hopeless.

We must not let the question of age interfere with operability. Last year we sent home a boy of twelve for

carcinoma of the rectum, and a man of seventy-four who had had abdominosacral removals of a carcinoma of the rectum. Neither must we interest ourselves too much in mortality figures. This has been stressed again and again. We have increased our operability from 54 per cent to 74 per cent, with a mortality in carcinoma of the colon of 9.6 per cent. It is very easy to keep the mortality low if the hopeless or dangerous cases are rejected, but we believe that operation should be performed on patients with metastases in their livers, even with quite extensive metastases in their mesenteries, if the primary lesions can be removed. This is an infinitely better operative procedure than the temporary or so-called palliative colostomy, which really does not palliate.

A word must be said regarding the Mikulicz operation — I do not mean this critically of Dr. Adams, but after all one must report his experience in order that everyone may make his own interpretation. Let us throw out the question of wound implantation of cancer in this operation. It does not occur, unless the old Mikulicz procedure is done and the living carcinoma is implanted in the wound. If the modified Mikulicz procedure is performed, with the excision of the carcinoma between clamps at the time of operation, wound implantation is impossible. We must therefore not think of wound implantation as one of the dangers of the Mikulicz procedure.

We have done so many Mikulicz operations and with such good results that I should like to show the dangers that we have encountered and that may occur to any of you. First, in resections of the splenic flexure almost nothing has ever been said about the danger of injuring the root of the mesentery next to the jejunum, which accounts for some deaths in operations of any type at this level. If the resection is carried down to the root of the mesentery, care must be taken to stop it before reaching the point where the jejunum becomes retroperitoneal. At this point the mesenteric root is thin and easily torn. It is extremely difficult to suture the mesenteric peritoneum at the root of the mesentery in the jejunal fossa. We have had an avoidable fatality from such sutures' tearing out, thus permitting the herniation of loops of jejunum through the resultant hole in the root of the mesentery. We therefore recommend that the resection of the mesenteric root here be always short. Where the mesentery surrounds the root of the jejunum, a good sized apron of mesentery should be left so that the edges can be readily approximated.

Another point of value in dealing with the Mikulicz procedure is that carcinomas of the sigmoid flexure are frequently situated so low that when they are removed not enough rectum and sigmoid are left for the operation to be accomplished. There will, however, not infrequently be a short stump of sigmoid and rectum which can be brought straight up to the skin. Several times in such cases it has been possible for us so to mobilize the splenic flexure that the descending colon could be brought down, placed parallel with the straight tube of sigmoid by bringing it down into the pelvis, then carried back up along this straight tube of sigmoid and rectum, to which it is attached by tacking sutures, thus forming the straight double barreled loop of the Mikulicz, which points straight into the pelvis. The result is an angulation of the upper segment of bowel at its lower point where it is kinked deeply within the pelvis, should postoperative distention occur, as it not infrequently does after this operation. Traction on the sutures at the angulated point of bowel will result, and in our experience has resulted in pulling out the sutures, with the production of leakage and of

peritonitis. We therefore feel that when this maneuver is undertaken, by which fecal streams can be restored even in some of the cases in which the lesion is low, a complete transverse ileostomy should be done so as completely to sidetrack any feces, thus preventing them from passing through this angulated point until the spur has been cut and firm union between the two loops has taken place.

Still another point which Dr Cattell has brought out is that in anchoring the colon in the wound in colostomies the peritoneum should never be sutured either to the mesentery or to the bowel itself. Instead, he has devised the scheme of tying into the last suture a tab of epiploic appendage as the peritoneum of the abdominal wall is sutured snugly about the bowel. This results in support to the opening which prevents it from falling back, and carries no danger of penetration of the tube of bowel wall, and consequent fecal soiling of the wound.

Several of our colleagues throughout the country have told us that they had trouble in closing the intestinal fistulas which follow the cutting of the spur, when patients return at the end of two months for closure of the colonic stoma in Mikulicz operations. We believe that much of this difficulty is due to failure to clean off thoroughly the edematous tabs of epiploic fat and to ligate adequately any indurated mesentery that extends above the levels of the fascia. When the intestinal tube of a secondary Mikulicz closure is to be turned in, it should be as free and flexible as normal bowel wall, in this condition it can be accurately inverted and closed with mattress sutures, so that there will be no danger of leakage.

Dr Cattell has likewise demonstrated that it is unnecessary in many of these cases to separate the tube of intestine from fascia and muscle, but that the closure can be satisfactorily made directly beneath fat and skin.

DR. ARTHUR W. ALLEN, Boston The question of whether we should operate on colon cases in one stage or in two warrants a few remarks from me, since I have recently been challenged by my good friend Dr Harvey Stone, of Baltimore, in an editorial in the October issue of *Surgery*. This happened to be published in the same week that my article came out in the *Journal of the American Medical Association* which advocated a two-stage procedure, particularly as it applies to the right colon, and tried to prove its advantages from statistics.

Dr Stone says he does not believe that we should rely on statistics but admits that he does not know what his own statistics are. It is extremely difficult for any one person to gain experience rapidly in this field. It will take any one who operates on these cases quite a while to find out what his own mortality is, whether he adopts a one stage or a two-stage procedure.

Between 1925 and 1936, surgeons at the Massachusetts General Hospital were definitely one stage minded, there is no getting around that. In spite of this we did 253 two-stage operations along with 400 one-stage ones. Most of them were done on the poorest risks—patients who were obstructed and elderly patients who arrived in bad condition. The 400 cases done in one stage represent the better risks but the mortality was 19.2 per cent, whereas that of the two-stage operations was only 13 per cent.

I am particularly interested in the more favorable tumor that occurs in the right bowel, where there is at least a 60 per cent chance of a five year cure, and where the operation is so easy. The patients are not obstructed and are often in excellent condition so that it is a temptation to operate in one stage.

All I ask is that you consider very carefully this mortality table 20 per cent died in the group of one stage resections of the right colon, while in 28 cases only 2 deaths

(7 per cent) occurred when the two-stage procedure was used.

Why should the two-stage procedure be more seriously considered? One hears of the double risk of anesthesia, of the double risk of infection, of the increased hospital stay and of the terrible psychic trauma to the individual who has to face two operations instead of one. Well, peritonitis is the leading cause of death in this field of surgery, and in the one stage procedure we lost 24 patients. In the very unfavorable group of obstructed and old cases done in two stages we lost 9. The assertion of a double risk does not seem to be borne out by these figures.

Pulmonary complications rank next as a cause of death. Many of these patients die of pneumonia or collapse of the lung. In the one stage cases we had 22 deaths from this cause, and in the two-stage group, with the double opportunity for a fatal result, there were only 6 deaths.

I beg you to think seriously about the increased safety in two-stage procedures, until you have had sufficient experience in this field so that you can decide definitely which patients can stand a one stage procedure, I ask you to be routinists and to do a preliminary operation in cases of large cancer of the bowel.

DR. CHARLES G. MINTER, Boston I should like to say a word about the neglected class of cases—the advanced, perforated lesions, with particular reference to the right colon.

Körte in 1913 analyzed over 200 cases and reported 7 per cent with perforation. In 1931, Bagen and Cox, reporting on 1500 cases, found 9.4 per cent with perforation. Some years ago we analyzed 73 cases at the Beth Israel Hospital in an attempt to find the reason for our high postoperative mortality. We found that 25 per cent of our cases showed perforation with either a large mass, abscess or internal fistula. Those cases, of course, represent the advanced stage. If you can drain the abscess and divert the fecal stream, it is sometimes remarkable what regression in growth takes place.

The first stage is drainage of the abscess—at the second stage I prefer a lateral ileotransverse colostomy made in the antiperistaltic direction and done through an incision on the left side of the abdomen. At the third stage, the second procedure will have had two effects: vaccination of the abdominal cavity on the right, and the formation of a barrier by postoperative adhesions with the root of the terminal mesentery, so that this portion of the abdomen is well protected. At resection during the third stage, a wide excision around the persisting fistula through the abdominal wall should be made. Further resections may have to be done, such as removal of a portion of the duodenal or gastric wall.

If the anastomosis is done in the antiperistaltic direction, there are two methods of procedure: the ends can be turned in, or if that seems to leave too long a blind loop, or if there is danger of opening the left side of the abdominal cavity, a closed type of Mikulicz can be done and the spur cut down, and later on closure of the fistula can be done in the wound. The lumen does not have to be large, as an adequate anastomosis has already been established by ileotransverse colostomy.

In the current year we have handled 3 such cases with out mortality. Of our last 6 cases, 5 have survived. The one fatality was an ill-advised attempt at one stage resection.

A case has recently come to my attention, that of a woman on whom I operated some years ago. A multi-stage resection was done, with removal of part of the duodenal wall and the perinephritic capsule. The woman

lived an active life for three and a half years or more, and died of uremia from recurrence in the right renal region. I feel that such a result gives a little encouragement for more intensive operative procedures on the late cases

DR PHILEMON E TRUESDALE, Fall River I should like to make one point in connection with anastomosis of the large intestine. Bearing in mind that the sphincter muscle of the anus is a shut-off valve, and that the afferent loop of intestine empties on the surface of the abdomen, the

contents of the bowel will pass in the direction of least resistance, which is through the colostomy. This opening will not close until the obstruction at the anus is removed. If the sphincter is cut or temporarily paralyzed by dilatation, closure of the colostomy will be greatly facilitated. In all anastomotic operations on the large intestine, I think it is wise to paralyze the constrictor muscle temporarily either by dilatation or by severing the external sphincter muscle, just as we do in operating for anal fistula.

A NEW CONCEPTION OF SERUM PHOSPHATASE

Review of Experimental Work

STEPHEN MADDOCK, M.D.,* S. J. THANNHAUSER, M.D.,† MAX REICHEL, PH.D.,‡ AND
JEROME GRATTAN, M.S.§

BOSTON

IN 1930 Roberts¹ reported an increase in serum phosphatase values in obstructive jaundice, subsequently he suggested that the phosphatase level could be used in the differential diagnosis of jaundice on the basis of there being a high value in the obstructive type and a low value in the hepatocellular type. Numerous studies of phosphatase in jaundice have been made during the past few years, and the material is well reviewed by Cantarow.³ Briefly, the present status of the subject is as follows. Numerous workers have confirmed the fact that extrahepatic biliary obstruction causes a rise in serum phosphatase both in human beings¹ and in dogs.⁵ But there is a great difference of opinion as to whether hepatocellular jaundice yields uniformly low values. Cantarow and Nelson⁶ in 1937 concluded that phosphatase determinations are of no value in differentiating these two types of jaundice, since high values are found in cases of hepatocellular jaundice caused by a proved toxic etiology. Flood, Gutman and Gutman⁷ in the same year, however, stated that the method is useful, inasmuch as a low phosphatase value definitely rules out obstruction of the extrahepatic biliary tree.

No logical explanation of the high phosphatase values in obstructive jaundice has yet been offered. Cantarow and Nelson⁶ write "It seems futile in the present state of knowledge to theorize regarding the possible mechanism of production of the increase in serum phosphatase in jaundice of obstructive and hepatocellular origin."

The purpose of this paper is to attempt an explanation of the mechanism involved, and to summarize for the clinician the essential facts of a

series of rather complicated experiments which have recently been reported in extenso elsewhere.^{8, 9, 10, 11, 12.}

EXPERIMENTS

The Activation of Serum Phosphatase with Ascorbic Acid Commencing with the fact that ascorbic acid was known to act as an activator or catalyst in proteolytic enzymatic reactions,^{13, 14} a series of test-tube experiments was performed to

Figure 1 Serum phosphatase values after common bile duct ligation, before and after activation

determine whether this effect might also be operative on the enzyme of serum phosphatase. It was found that ascorbic acid was an intense activator of serum phosphatase. After a large number of tests had been done, the optimal conditions were determined as a proportion of 5 mg. of ascorbic acid to 1 ml. of serum.

*From the Surgical Research Laboratory of the Boston City Hospital and the Boston Dispensary.

§Associate professor of chemistry, Tufts College Medical School.

bic acid to 0.1 cc of blood serum, using β -glycerophosphate at a pH of 8.9 as a substrate. The activation was immediate, and showed no increase after the first hour. Accordingly, all readings were made after one-hour incubation at 37°C and all subsequent tests were made under the optimal conditions defined above. Numerous tests showed that normal human, dog or cat serum on activation contained from one hundred to two hundred times as much phosphatase as had ever before been suspected. The phenomenon of activation by ascorbic acid was then used to study pathologic human serums and those of animals under various controlled experimental conditions.

Experimental Biliary Obstruction Beginning with the simplest experimental situation, the common bile duct was ligated in 11 dogs, and blood samples were studied at frequent intervals. In each instance the serum phosphatase level rose steadily, and in from ten to fourteen days reached a maximum of 80 to 100 units,* as previously described by Bodansky and Jaffe.⁵ When the serum from these dogs was activated with ascorbic acid, instead of the two-hundred-fold increase in activity noted in normal samples the values rose only to the general level procured by activation of the preoperative sample. A typical experiment is shown in Figure 1. The serum before common bile duct ligation showed 125 units, which on activation with ascorbic acid rose to 205 units. On the seventh postoperative day the dog's serum contained 80 units by the ordinary test, and on activation with ascorbic acid the value rose to 197 units. This indicated that the rise in phosphatase noted after biliary obstruction was due to an increased activation of the serum phosphatase, and not to an actual increase in the amount of circulating phosphatase, as had always previously been supposed. If there had been an actual increase in amount of phosphatase the value on activation should have increased from 80 to 1600 units. It was thus evident that retention of bile caused the increased activation, but the identity of the activator was unknown.

Effect of Parathyroidectomy on Blood Phosphatase in Biliary Obstruction In order to determine the possible influence of parathormone, so evident in osteitis fibrosa cystica, on the activation of serum phosphatase, an experiment was performed in which ligation of the common bile duct of a dog was combined with complete thyroparathyroidectomy. This animal showed the typical syndrome of parathyroid deprivation. Tetany was prevented

by the intravenous administration of calcium gluconate. The rises in serum phosphatase were in the same order of magnitude as those noted in bile duct obstruction alone. Activation of the serum with ascorbic acid showed a response which was also identical. It seemed justifiable to conclude from this experiment that the parathyroid glands are not necessarily involved in the production of high phosphatase value, and do not enter in any obvious manner into the equation in biliary obstruction (Fig 2).

Experimental Complete Biliary Fistula So as to study the behavior of serum phosphatase under conditions just the reverse of biliary obstruction, a

Figure 2 Serum phosphatase values, after common bile duct ligation and thyroparathyroidectomy, before and after activation

series of 12 dogs with a biliary fistula was prepared. In these animals the common bile duct was ligated and a mushroom catheter was inserted into the fundus of the gall bladder. The end of the catheter was brought out through a stab wound in the abdominal wall and connected to a sterile balloon. It was thus possible to collect all the bile excreted each day, and to study its phosphatase content, as well as that of the blood serum.

The serums of these animals gave the surprising result of an increase in phosphatase to from twenty to thirty times the normal preoperative level within two or three days after operation. On activation of the serum with ascorbic acid the same phenomenon noted with obstructed dogs occurred, that is, the increase in activity was limited to the level found before operation. This indicated that the increase in serum phosphatase after biliary fistula was also due to an activation of the enzyme, and not to an increase in the total amount of phosphatase (Fig 3).

In order to avoid repetition the term unit throughout this paper is used to designate the Bodansky unit. The latter is that amount of phosphatase contained in 100 cc of serum which will hydrolyze 1.0 mg of phosphorus from the substrate β glycerophosphate at a pH of 8.9 at 37°C. in one hour.

The Phosphatase Content of Bile Bile taken from the gall bladders of normal dogs was found to contain from 25 to 55 units of phosphatase per 100 cubic centimeters. Daily determinations of bile from the dogs with a biliary fistula showed no significant variations from the normal amount, nor did the general condition of any dog vary greatly during the course of the experiment. When

Figure 3 Serum and bile phosphatase values, in cases with complete biliary fistulas, before and after activation

ascorbic acid was added to these bile samples, very little increase (about 20 per cent) in phosphatase activity was found, indicating an almost complete activation of gall-bladder bile at all times. It thus seemed that the bile contained the activating substance.

The Effect of Ascorbic Acid on the Activation of Human Serums with High Phosphatase Activity With the purpose of studying the degree of activation of the serum phosphatase in human beings, ascorbic acid was added to the serums of normal individuals and to those of patients with high phosphatase values. It was found that normal serums responded with an increase in activity up to from 100 to 135 units. The serums with high initial values failed to show such striking rises. For example, in 1 case of Paget's disease the initial value was 48 units, and on activation with ascorbic acid rose only to 105 units. These results indicated that in diseases showing high serum phosphatase values the situation is the same as in the experimental animals, that is, one of increased activation of phosphatase, and not an actual increase in the total amount of the enzyme present in the serum.

The Effect of Bile Acids on Serum Phosphatase Activity In an effort to determine the role played by the bile acids in the rise of serum phosphatase

in biliary obstruction, a series of experiments was performed *in vitro*. It was found that the addition of sodium desoxycholic acid produced a marked inactivating effect on serums with high phosphatase values. This inactivating property of bile acids on phosphatase had previously been noted by Takata.¹⁵ It had also been known since 1933 that other substances containing the sulphhydryl (SH) radicle had a similarly depressing effect on phosphatase activity.¹⁶ Experiments *in vitro* with glutathione and cystein showed that these substances had an inactivating effect on phosphatase which was much greater quantitatively than the effect of ascorbic acid as an activator. Experiments *in vivo* with dogs and patients suffering from Paget's disease showed that the intravenous injection of cystein brought about a temporary drop in the serum phosphatase. It was not possible to bring about changes of the magnitude observed in the test-tube experiments, but a definite temporary decrease in phosphatase values was noted.

The important feature of these experiments was the demonstration that the effect of retained bile acids was a lowering of the phosphatase activity, while dogs and human beings with complete biliary retention showed an increase in phosphatase activity in the blood. This finding pointed to the existence of some other substance in the body which activates the phosphatase in the serum, and which must be present in sufficient amounts to overcome easily the effect of bile acids. This assumption of the existence of an activating substance also reconciled the seemingly paradoxical increase in phosphatase in dogs with a complete biliary fistula. In these experiments the draining off of bile acids resulted in a predominance of the activating factor.

The Nature of the Activating Substance The nature of the activating substance may be assumed to be analogous to the coenzyme systems already described by Warburg,¹⁷ von Euler,¹⁸ Kuhn,¹⁹ Meyerhof,²⁰ and others. These investigators have demonstrated the existence of a cozymase which enters into the reaction in the carbohydrate metabolism of muscles.

According to Warburg¹⁷ and von Euler,¹⁸ the cozymase in this system is a definite crystalline chemical compound consisting of a combined phosphoric ester of the amide of nicotinic acid, a pentose and phosphoric acid.

The exact nature of the cofactor or coenzyme in the serum phosphatase reaction has not as yet been determined. Certain additional facts about it, however, are known. In recent experiments²¹ it has been demonstrated that the addition of 0.1 cc of serum from dogs with biliary obstruction or from patients with Paget's disease to 0.5 cc

of normal serum will cause an increase in the splitting of phosphates of from 200 to 400 per cent. In other words, the pathologic serums contain a substance which has the same activating power as ascorbic acid, but differs inasmuch as its maximal effect is not reached until after twenty-four hours of incubation. Ascorbic acid reaches its maximum in one hour. The activating substance or cofactor can be demonstrated in dialysates of the serum from dogs with biliary obstruction.

DISCUSSION

The most significant conclusion of clinical import that can be drawn from all these experiments is that what has always been regarded as an increase in amount of serum phosphatase in disease is not an actual increase in enzyme, but merely an activation of pre-existing enzyme normally present at all times and in all the animals studied. This necessitates an alteration in our fundamental concept of phosphatase in both normal and pathologic states. The relation of serum phosphatase and bone phosphatase to the growth and repair of bone may well be involved.

It is doubtful whether the discovery of substances such as cystein or glutathione which depress phosphatase activity will be of any practical use in the treatment of Paget's disease, and of other conditions known to have high phosphatase values in the serum. Careful studies on a patient with osteitis fibrosa cystica from whom parathyroid adenomas had been removed surgically were made by Bauer.²² By following the serum calcium-phosphorus ratio and the phosphatase after operation, together with biopsies of the bone, Bauer found that the serum phosphatase remained elevated postoperatively until all evidence of osteoblastic activity had ceased. He concluded that the high phosphatase was an index of osteoblastic activity, and as such was a normal physiologic concomitant of bone-building. If this theory is correct it would be unwise to attempt to lower the phosphatase artificially in Paget's disease, since it might interfere with reparative processes. But this raises the fundamental question of which is primary and which secondary.

The mechanism of increased serum phosphatase in jaundice seems to be understandable in the light of the results given here. Any obstruction to the excretion of bile results in the damming up of both depressing (bile acids) and activating (cofactor) substances. Since the cofactor is more powerful as an activating agent than bile acids are as depressors, the net result is an increase in activity of

serum phosphatase. The difficulty of attempting to use phosphatase determinations in the differential diagnosis of liver disease is thus apparent.

It has been shown in these experiments that phosphatase activity must represent the outcome of reactions in a complex system consisting of enzyme, cofactor, oxidation-reduction potential and substrate. Thus the phenomenon is analogous to the cozymase system described by Warburg and von Euler. Our experiments demonstrate that human disease may originate from disturbances in enzymatic activity either from a deficiency or from an excess of any of the factors in the system.

CONCLUSIONS

Elevation in serum phosphatase as seen in clinical and experimental pathologic conditions is due to an increased activation, and not to an actual increase in the amount of this enzyme present in the circulating blood. This increased activation results from the presence of a coenzyme, the exact nature of which has not as yet been determined.

PAPERS FROM THE FAULKNER HOSPITAL

THE USE OF COMBINED PONTOCAINE AND NOVOCAIN
FOR SPINAL ANESTHESIA

SIDNEY C. WIGGIN, M.D.,* AND JOSEPH TARTAKOFF, M.D.†

BOSTON

FOR the past four years at the Faulkner Hospital, pontocaine and novocain have been combined for spinal anesthesia in 1500 cases to the exclusion of all other agents. This practice followed the experiences of Lundy and Essex of Tovell and of McCuskey, who advocated this combination for anesthesia below the level of the umbilicus. This method has apparent advantages of safety and efficiency which our use of spinocain, novocain and pontocaine separately had not given since the return of spinal anesthesia in surgery in 1928. In our hands pontocaine-novocain anesthesia has been highly satisfactory, and thus far no fatalities have been directly attributable to it.

Spinocain was discarded in 1929, after a year's trial, as too depressing to the circulatory and respiratory systems, and also as unreliable in the development of anesthesia. Novocain crystals dissolved in spinal fluid were used in doses of from 50 to 300 mg. until 1933. It was difficult to obtain anesthesia lasting from one to two hours with novocain alone, however, and the incidence of nausea and vomiting was considerable, with an initial drop in blood pressure in the large majority of cases. In 1932 pontocaine alone was tried. While the anesthesia thus gained was satisfactory in depth and duration, with minimal disturbance of the clinical course, there were definite drawbacks: anesthesia did not invariably follow its injection, the level of anesthesia not infrequently fell short of one's expectation, the onset of anesthesia was often delayed from five to twenty-five minutes, and complete sensory anesthesia was not obtained in all cases. In a few cases sudden respiratory failure developed.

The specific gravity of the combination of pontocaine and novocain with the spinal fluid is definitely greater than the specific gravity of the fluid itself, as is shown clinically by the fact that anesthesia develops in the dependent side of the patient as he lies on the table after the injection.

In terms of the anesthetic effect, 1 mg. of pontocaine used alone is said to be the equivalent of 10 mg. of novocain. But when pontocaine and novocain are used in combination the anesthetic effect is actually different. For example, 200 mg. of novocain will give sufficient anesthesia for a

gall bladder operation lasting up to one hour, but 10 mg. of pontocaine mixed with 100 mg. of novocain (which according to the above equivalents should equal 200 mg. of novocain) will give skin anesthesia only to about the level of the lower ribs, which is sufficient for a hysterectomy or appendectomy. Twenty mg. of pontocaine alone (theoretically equal to 200 mg. of novocain) will give anesthesia to the level of the clavicle, which permits operations in the upper abdomen lasting one and a half or two hours. Anesthesia of the same level and duration is, however, produced by 14 or 18 mg. of pontocaine in combination with 100 mg. of novocain (see Table 1), and with fewer toxic symptoms than would be produced by the 200 mg. of novocain which we have used as a standard of comparison. These facts indicate that the combination of the two agents in spinal fluid, through some synergistic effect not as yet clearly understood, reduces their toxicity, and produces a slighter fall in blood pressure than does either agent alone, less nausea and vomiting than does novocain alone, and less interference with respiration than does pontocaine alone. The combination, then, enhances the desirable effects of each drug, and avoids the major disadvantages of either used singly.

The onset of anesthesia with the pontocaine-novocain mixture is approximately as rapid as that with novocain alone, varying from one and a half to five minutes. The desired level of anesthesia governed by the dose and technic of administration is gained within this period, and sensory loss is complete. The duration of the anesthesia is approximately the same as that gained with pontocaine alone, or twice that gained with a comparable dose of novocain alone.

CONTRAINDICATIONS

This method of spinal anesthesia has been employed in all types of operations below the diaphragm, in well-selected cases. The chief contraindications to its use are the same as are recognized in general for spinal anesthesia, namely markedly debilitated states caused by acute or chronic disease, shock, hemorrhage and sepsis, hypotension of pathologic origin, hypertension with cardiac or renal disease (contraindicates high spinal anesthesia only), severe cardiac conditions (contra-

*Anesthetist in-chief, Faulkner Hospital.

†Assistant anesthetist, Faulkner Hospital. Assistant in surgery, Tufts College Medical School.

indicates high spinal anesthesia only), vertebral disease (prevents lumbar puncture), and local sepsis at the site of the lumbar puncture. There are no general contraindications to this method of spinal anesthesia for operations requiring only 50 mg of novocain and 5 mg of pontocaine, or less.

PREPARATION OF THE PATIENT

The night before operation the patient should receive some form of hypnotic to produce a good night's sleep, such as 3 gr pentobarbital-sodium, with a glass of orange juice at 8 o'clock. Two hours before operation this dose of pentobarbital-sodium is repeated. One-sixth grain morphine sulfate and 1/200 gr scopolamine are given one hour before operation to the average patient. These dosages must be varied according to the age, sex, weight, and psychic and physical condition of the patient. The patient should arrive at the operating room in a very drowsy, amnesic state.

TECHNIC OF ADMINISTRATION*

For the administration of anesthesia with pontocaine and novocain, the variable factors to be considered are the site of injection, the dilution of the agents in the spinal fluid, the dosage to be employed, the rate of injection, the position of the patient and the supplementary anesthetic measures.

Site of Injection. The second to third lumbar interspace is used almost routinely for injection. In lower-extremity operations or operations below the umbilicus in poor-risk patients, the third to fourth lumbar interspace is chosen. If the patient is in good physical condition and there is difficulty of puncture at the second to third lumbar interspace, the first to second interspace may be used.

Dilution of Agents. The concentration of the pontocaine and novocain in solution with the spinal fluid is of great importance in lessening the toxic effects. The greatest danger in spinal anesthesia is the use of highly concentrated solutions of the agents. The dosage of the agents should be kept at a minimum considering the individual's physical condition and the type of operation. The dilution of the mixture with spinal fluid is based on an allowance of 1 cc of spinal fluid for each 50 mg of novocain.

Dosage to be Employed. To simplify the estimation of dosages, 50 mg of novocain is now used, with varying dosages of pontocaine to obtain height and duration of anesthesia, for operations below the level of the umbilicus, and 100 mg of novocain,

with varying dosages of pontocaine, to obtain anesthesia above the umbilicus (Table 1). The age, size and physical condition of the patient, as well as the type and approximate duration of the operation, are considered, and postoperative pain is also allowed for. If the calculation of the dosage of pontocaine and novocain is based on the average-sized adult, 10 mg of pontocaine with 100 mg of novocain gives anesthesia to the nipple line, lasting for two and a half or three hours in the superficial structures, as in double herniotomy. These dosages are insufficient to give anesthesia for the deeper structures, in which pain is conditioned by

Table 1 *Standard Dosages for Normal Adults as Used at the Faulkner Hospital*

OPERATION	NOVOCAIN mg	PONTOCANE mg	AVERAGE TIME OF ANESTHESIA		SPINAL FLUID cc
			DEEP STRUCTURES hr	SUPERFICIAL STRUCTURES hr	
Hemorrhoids dilatation and curettage pro- state, perineal repair deliveries	50	5-8	1 ¹	2	1.0
Cesarean section hernia (single)	50	8-10	1	1 ¹	1.5
Hernia (double) ne- phrectomy	100	10	2	2 ¹ 3	2.0
Appendectomy	100	8-10	1 ¹	1 ¹ 2	2.0
Gall bladder stomach intestines	100	14-18	1 ¹	2 ¹	2.0
Hysterectomy	100	12	1 ¹ 2	2	2.0
Lower extremities	50	5	1 ¹	2	1.0
	50	10	2	2 ¹	1.0

nerves at higher spinal levels and by sympathetic nerve plexuses. For the anesthesia of deep structures, such as the gall bladder and stomach, 12 to 14 mg of pontocaine in women and 14 to 18 mg in men is required with 100 mg of novocain. This mixture will give an anesthesia duration of from one and a half to two hours.

Rate of Injection and Position of Patient. In the administration of this combination only slight variation from standard methods has been made. Induction of anesthesia is made with the patient on his side, the operating table level and the head on a small pillow. Ephedrine sulfate (50 to 100 mg in 1 to 2 cc of 1 per cent novocain) is injected subcutaneously into the second to third or third to fourth lumbar interspace level. Lumbar puncture is then performed with a 22-gauge gold needle, introduced through a Mason thumbtack introducer. In accordance with the dosage chart the proper amount of spinal fluid is withdrawn into a 10-cc syringe, the novocain crystals are dissolved by this fluid, and the proper amount of pontocaine is added. This combination is injected without barbotage into the subarachnoid space at a rate of 0.5 cc per minute. As soon as the injection is completed the patient turns himself so that he is lying on his back, keeping his head on the pillow. This maneuver facilitates the diffusion of the pontocaine-novocain solu-

*The present technique of administration and the dosage chart differ somewhat from those given by the author in Chapter VI of *Mason's Preoperative and Postoperative Treatment* (Philadelphia: W. B. Saunders Company 1957).

tion in the spinal canal. In order to prevent any possibility of the spinal agents' working cephalad, the Trendelenburg position is not allowed for fifteen minutes. The blood pressure, pulse and respirations are recorded every five minutes. If the diastolic blood pressure approaches 20 mm of mercury, 0.2 cc adrenalin (1:1000) is injected intramuscularly to maintain or elevate the pressure. If the fall in blood pressure is due to surgical shock from loss of blood, 5 per cent glucose in saline is given intravenously, with a citrated blood transfusion in addition if the condition requires it.

Supplementary Anesthetic Measures Spinal anesthesia must be supplemented by other technics if the operation extends beyond the duration of the anesthesia, or if the patient is a borderline operative risk.

If the operation is protracted, so that the anesthesia wanes, the earliest signs of pain or discomfort or of spasm of the abdominal muscles demand that the anesthesia be supplemented by cyclopropane or nitrous oxide and oxygen. Sufficient ether is then added to obtain adequate relaxation, but the addition should be made with caution. Unless complete oxygenation is assured, it is dangerous to supplement spinal anesthesia with a deep nitrous-oxide and oxygen anesthesia, or to add ether hastily to this mixture in the first half hour, since anoxemia may be produced with resultant respiratory paralysis.

If the patient is a borderline operative risk requiring an upper abdominal or prolonged intra-abdominal operation—cholecystectomy or resection of the stomach or rectum—the dose should be kept at a minimum, not to exceed 10 mg pontocaine and 100 mg novocain. In the borderline-risk patient the attaining of complete height and duration of anesthesia by means of larger doses should not be attempted. The spinal anesthesia should instead be at once supplemented with cyclopropane and oxygen, which may be in turn supplemented by ether and oxygen (500 cc per minute), administered by the carbon-dioxide absorption technic throughout the operation. Nitrous oxide may be used in place of cyclopropane. After the peritoneum has been closed the inhalation anesthetics are completely removed and 100 per cent oxygen is administered, with re-breathing. The large majority of patients almost regain consciousness, with reflexes well established, before leaving the operating room. Postoperatively there is little nausea, vomiting or restlessness, and no untoward complications. The results in the cases handled by this method have been highly gratifying. This technic gives the surgeon the benefit of the complete relaxation of a maximum high spinal anesthetic through the use of minimum doses of pontocaine and novocain, with complete control of the

patient's oxygenation, and of a minimal amount of ether.

POSTOPERATIVE CARE

We believe that the immediate postoperative care should be under the control of the anesthetist just as is the care before and during the operation. The patient is kept level in bed for three hours, the head of the bed is then slowly elevated to a 30 degree angle. For the more effective prevention of pulmonary complications, the nurse is instructed to turn the patient from one side to the other every hour, and to have him inhale slowly and exhale rapidly twelve times on awakening. The blood pressure is recorded every fifteen minutes for three hours, or until it maintains itself at a normal level. Unless contraindicated, 500 cc. of 5 per cent glucose is given by rectum at once and 250 cc of saline is given rectally every four hours until the patient is able to retain fluids by mouth. If it is desirable to give a hypodermoclysis, the anesthetized legs are a very satisfactory site. Patients in poor physical condition are given from 750 to 1000 cc of 5 per cent glucose intravenously after the induction of anesthesia, during the operation, or immediately after it. The injection of intravenous fluid may be repeated every six or eight hours, a citrated blood transfusion may be added if necessary.

SUMMARY

Pontocaine and novocain in combination have been used exclusively in spinal anesthesia at the Faulkner Hospital during the past four years, the total number of cases so anesthetized being 1500. No fatalities directly attributable to the spinal anesthesia have occurred. Whereas each of these drugs used alone in spinal anesthesia has certain undesirable effects, the combination minimizes the disadvantages of each and enhances the desirable features of both.

The technic of management of patients undergoing spinal anesthesia is described.

THROMBOANGIITIS OBLITERANS OF THE SPERMATIC CORD

JOSEPH TARTAKOFF, M.D.,* AND J BEACH HAZARD, M.D.†

BOSTON

CASE REPORT

THROMBOANGIITIS obliterans has, from Buerger's¹ earliest publications, been considered very largely a disease of the extremities. This emphasis reached a degree that justified many reports in which it was attempted to prove that the disease involves the general vascular tree. This contention, however, had not originally been denied by Buerger. He says by way of definition "At the onset, thromboangitis obliterans is essentially an inflammatory process, involving particularly the deeply situated and larger arteries and veins of the lower and upper extremities." However, he further states "Although no extensive study has been made of thromboangitis in the vascular domain outside of the extremities, the typical lesions have been observed by the author in the spermatic vessels, and according to Murphy are said to occur in the renal vessels." Among the earliest supporters of this view, Barron and Linenthal² came to the following conclusion "This disease is not confined to vessels of the extremities, as is generally accepted, but is a generalized disease which may affect any part of the arterial tree, including the coronary arteries, the abdominal arteries and the arteries of the brain." Birnbaum, Prinzmetal and Connor³ described a case with very extensive dissemination of lesions, including the suprarenal, retinal, cerebral, pulmonary, coronary, mesenteric, pancreatic, hepatic, renal, duodenal and prostatic vessels. Excellent discussions of coronary-vessel involvement have been published by Mallory⁴ and Eppinger.⁵

In 1928, McGregor and Simson⁶ published a very illuminating report. Their patient was a Russian Jew, aged twenty-eight, who proved to have thromboangitis obliterans of the left spermatic cord. An orchidectomy was done, and the microscopic sections afforded an excellent opportunity for studying the early acute form of the disease. We wish to stress that surgery in cases of Buerger's disease of the spermatic cord affords an excellent opportunity of obtaining uncontaminated material for investigative work. It is for this reason, and for the purpose of directing attention to a lesion which is not considered in the differential diagnosis of diseases of the spermatic cord, that this report is made.

A Russian Jew, aged 28, presented symptoms of a dragging sensation and tenderness in the left groin and the left half of the scrotum, of less than 4 weeks' duration. There had been a gradual onset of the dragging sensation, which was later accompanied by tenderness. These discomforting symptoms soon became incapacitating. General good health continued, however, and the patient suffered neither chill nor temperature elevation. There were no abdominal manifestations or genitourinary symptoms.

The patient had been an habitual user of tobacco to excess in the form of cigars and cigarettes since early adult life. The past history was otherwise negative. All possibility of venereal disease was denied.

The patient's father and mother, both in the 7th decade, had hypertensive heart disease and diabetes, respectively. His wife and two children were alive and well. One sister of middle age was in good health and one brother, aged 32, was under treatment for duodenal ulcer. Another brother had died several years previously at 29, with a clinical diagnosis of acute coronary disease.

Physical examination revealed a generally well person with normal pulse and temperature. Locally there was moderate tenderness of the left spermatic cord, and a palpable mass the size of a cherry in the cord about 1 cm above the epididymis. The testis and epididymis felt normal and were non-tender. The cord above the nodule mentioned presented no tenderness, and there was no suggestion of thickening or induration. No difficulty was encountered in isolating the ductus deferens. The right cord, testis and epididymis were normal, and there was no involvement of the tissues of the scrotum. The prostate was normal to palpation.

The white-blood-cell count was 6350 with 75 per cent polymorphonuclear neutrophils, 1 per cent eosinophils, 1 per cent monocytes and 23 per cent lymphocytes. The red blood-cell count was 5,200,000 with a hemoglobin of 108 per cent (Sahli), the blood smear was normal. Examination of the urine was essentially negative. A blood Hinton test gave a negative reaction.

Under general anesthesia the mass was removed, it proved to be a matted segment of the pampiniform plexus and associated arteries. The testis and epididymis and the cord above the involved area were normal in appearance. The mass was adherent to the ductus deferens, but separation was effected without difficulty.

Convalescence was uneventful, and there was no residual induration of the cord. On two occasions, however, after periods of sexual activity there has developed generalized edema of the scrotum and tenderness at the operative site. At the present time (2 months after operation) there is no suggestion of recurrence. Examinations have revealed no evidence of vascular disease in the extremities.

Pathological Report

Gross examination showed the specimen to be roughly ovoid, with irregular surfaces. It was of firm but pliable consistence, white, and measured 1.5 by 1 by 0.6 cm. Sectioning revealed a moist, glistening, white to grayish white

cut surface with scattered small purplish red and brownish areas 0.5 mm or less in diameter.

Microscopic examination revealed veins varying from 0.3 to 1.3 mm in diameter, with occluding lesions. Only arteries less than 0.17 mm in diameter (arterioles) were present. The smaller vessels, including the arterioles, presented patent lumens and normal lining surfaces and vessel walls.

Characteristic lesions were found in a zone within the vessel lumen, adjoining the lining surface and apparently replacing the intima. These consisted of focal accumulations of mononuclear cells and frequent giant cells of foreign body type (Fig. 1), often with abundant cyto-

Figure 1 A zone of mononuclear cells focally arranged and with foreign body giant cells lines the intimal surface of a vein. On the left is a thrombus infiltrated with polymorphonuclears and on the right the vein wall. 200X.

plasm and fairly evenly distributed nuclei. These foci blended with each other, in some instances so as completely to line the vessel lumen. No necrosis was evident in these cell collections in any location. In several places the thrombus in the central portion of the vessel revealed disintegration of the fibrin and collections of polymorphonuclear neutrophils and fragmented nuclei. Other occluding masses were formed of partly organized thrombi, or organized and partly canalized thrombi with an occasional giant cell of foreign body type near the margin (Fig. 2). Of the 36 cross-sections examined, 3 showed healed lesions as last described. Clumps of hemosiderin were deposited here and there in the connective tissue.

The media of the veins were infiltrated in most instances by numerous polymorphonuclear neutrophils and varying numbers of eosinophils. No necrosis of the smooth muscle was present. Verhoeff's special stain showed the elastic tissue to be unaltered. The intervascular stroma presented an increase in connective tissue and was infiltrated by fairly numerous eosinophils and some polymorphonuclear neutrophils and lymphocytes in patchy distribution. The latter in places were clustered about small venules. Scattered clumps of hemosiderin were present. No tubercle-like lesions and no zones of necrosis were found in this intervascular zone. Sections stained for *Mycobacterium tuberculosis* and by the MacCallum and Goodpasture, and Gram-Weigert methods revealed no bacteria. Tissue properly fixed for the Levaditi stain was unfortunately not available.

Tissue fragments cultured in blood bouillon showed no growth.

Diagnosis: thromboangitis obliterans of spermatic cord.

The most typical histologic lesions in the section are focal accumulations of mononuclear cells with giant cells of foreign-body type in the vessel lumen and with purulent foci in the associated thrombi. Mallory¹ has pointed out that the cells forming the focal accumulations are prone to be arranged in perpendicular rather than concentric fashion as seen in typical tubercles. Both tuberculosis and syphilis are extremely apt to produce tubercle-like lesions outside the vessel wall. No zones of caseous necrosis as found in tuberculosis are evident in any focal mononuclear accumulation. The areas of infarct necrosis so often occurring with syphilis are not found, and no obliterative endarteritis is evident in the small vessels. In

Figure 2 A vein lumen is obliterated by an organized partly canalized thrombus. A foreign body giant cell is present near one margin of the occluding mass. 45X.

thrombosis of nonspecific type, a thrombus appearing as described may occur, but in no such case is a tubercle-like lesion likely to be found in the vessel lumen. Sarcoid (Boeck's disease) would be likely to produce tubercle-like lesions outside the vessel wall. In view of the above considerations a diagnosis of thromboangitis obliterans seemed warranted.

DISCUSSION

Thromboangitis obliterans must be included in the differential diagnosis of diseases of the spermatic cord. The entity with which it is most likely to be confused is tuberculosis of the epididymis and ductus deferens, because of the latter diagnosis, in cases reported by Buerger¹ and McGregor and Simson,⁶ orchidectomy was performed. Chronic gonorrheal epididymitis and funiculitis

would prove difficult to differentiate clinically, and the diagnosis might depend on the demonstration of the characteristic intraluminal lesions of thromboangitis obliterans. Nonspecific thrombosis of the spermatic venous plexus would produce a considerably more extensive lesion than the one which was encountered. Benign and malignant neoplasms and the common spermatocele, hydrocele of the cord and varicocele should cause little confusion.

Unfortunately, there is no precedent on which to base an opinion as to prognosis. None of the few cases reported in the literature were followed long enough to indicate their course. If a parallel is to be drawn between the disease in the cord and in the lower extremities, some extension along the course of the pampiniform plexus and its associated arteries may be expected. By the same analogy, the development of similar lesions in other vascular beds might be anticipated. One report⁶ raises the possibility of gangrene of the testis, but this is doubted since deliberate section of the cord in hernioplasties, as done on the senile, is followed by progressive atrophy of the testis but not by infarct necrosis. The collateral circulation derived from the scrotal sac is adequate to protect the organ.

Therapy, on the basis of the pessimistic outlook in regard to recurrence⁴ in the spermatic cord, should consist in complete removal of testis and cord if the diagnosis is established before or at the time of operation. If, as in this case, local removal is carried out for biopsy purposes, any secondary procedure indicated because of residual tissue or

recurrence should be radical, that is, orchiectomy. Since the relation of localized lesions to distant development of the disease is not known, even this more radical treatment might fail to halt the progress of the malady.

The measures used in the treatment of conventional thromboangitis obliterans are largely directed toward increasing circulation, but in the localization of the disease considered here this method has little to offer. Total abstinence from tobacco is advisable as a possible preventive measure.

SUMMARY

- 1 A case of thromboangitis obliterans of the spermatic cord is reported.
- 2 Typical histologic lesions of the acute stage of the disease are described.
- 3 The importance of including thromboangitis obliterans in the differential diagnosis of lesions of the spermatic cord is emphasized.
- 4 Possibilities of prognosis and therapy are considered.

CORONARY OCCLUSION IN A YOUNG ADULT

DAVID HALBERSLEBEN, M.D.*

BOSTON

THE last twenty years, and especially the last ten years, have seen a rapid development in the clinical diagnosis of coronary occlusion. A disease of vascular degeneration, it is encountered infrequently in patients below the age of forty, and rarely in patients below thirty.¹ Under such circumstances the clinician is tempted to doubt the logical conclusion reached after hearing the patient's story. He is apt to ascribe the accuracy of details to a previous knowledge by the patient of the condition in some other person, for lay knowledge of the disease has also spread widely. The electrocardiographic tracing may be of great value under these circumstances in confirming the diagnosis, which would otherwise be doubted because of the youthfulness of the patient.

Physician, Faulkner Hospital

Owing to the rarity of coronary occlusion in young people, it seems worth while to report a proved case.

CASE REPORT

Mrs. J. K., aged 28, entered the Faulkner Hospital on May 31, 1937, because of pain in the chest. On May 28, while sitting at a table, she was suddenly seized with pain in the middle of the front of her chest. The pain was severe and radiated to both shoulders, both arms, the upper back, the neck and both sides of the jaw. There was slight palpitation. She said that she felt as if she were going to die.

The mother was living and well at the age of 51, the father living and well at 53. Blood pressure determinations on the two in October, 1937, were 130/75 and 150/80 respectively. There was no evidence of vascular disease in other members of the family.

The patient had been a healthy young woman. Measles, chickenpox and whooping cough had been the only infec-

tuous diseases of childhood. A blood pressure reading of 145/90 was obtained at 21. During a pregnancy at 26 the tension varied between 130/80 and 160/90, with the majority of the readings 150/85. Only one of several specimens of urine examined during the pregnancy showed the slightest possible trace of albumin. The blood pressure was 145/90, 2 months after delivery. On May 14, 1937, when the patient consulted her physician because of pregnancy, the blood pressure was 150/85 and the pulse rate 96. Her last menstrual period had started on March 16.

Her physician saw her within an hour of the onset of pain. She appeared apprehensive and somewhat pale. The oral temperature was 98.6°F, pulse rate 80, respirations 16 and blood pressure 140/80. Examination of the heart, lungs and abdomen revealed nothing abnormal. Sedatives were given. The patient was carefully re-examined on the four following days. She continued so apprehensive of death as to seem hysterical at times. The oral temperature did not rise above 98.6°F, the pulse rate above 86 (and it went as low as 64), and the blood pressure varied between 135/75 and 125/70. The heart sounds were normal, without gallop or friction rub. Breath sounds on each side of the chest were normal. The lymph nodes were not enlarged, and the spleen was not felt.

Two specimens of urine had a specific gravity of 1.025 and 1.028 respectively, but contained large amounts of albumin. The hemoglobin was 90 per cent (Sahl), and the red blood cells numbered 4,500,000 per cu mm. The white blood cells were 32,000 per cu mm, with 6 per cent polymorphonuclears, 15 per cent lymphocytes, 1 per cent eosinophils and 78 per cent young cells resembling monocytes, which were mostly oxidase positive. There were 3 per cent nucleated red cells, and the platelets were slightly decreased. The blood Hinton reaction was negative.

Stereoscopic x rays of the chest with careful fluoroscopic examination of the mediastinum showed no abnormalities.

An electrocardiographic tracing made on June 1 showed a low take-off of the S-T curve in Lead 1, and a high take-off in Leads 2 and 3. The QRS complex was notched in Lead 2. T waves were diphasic in Leads 2 and 3. On June 2 the take-off of the S-T curve in Lead 1 was not so low as the day before. A tracing made from a chest lead, with the electrode at the apex, showed a Q wave.

The pain recurred occasionally throughout each day of the illness, though most of the time it was slight. On June 2 the patient was found distraught with pain, which eased in a few minutes, the patient lay back to rest. Twenty minutes later she was found extremely cyanotic and died promptly.

Autopsy examination by Dr. J. Beach Hazard confirmed the clinical diagnoses of acute myocardial infarction and leukemia.

The heart was enlarged, weighing 410 gm. The posterior half of the left ventricular wall was pale brownish-yellow from within 1 cm. of the mitral ring to the apex, and was thinned to 0.9 cm. as compared with 1.9 cm. elsewhere. There were mural thrombi in the right ventricle. Beginning 18 cm. from its origin, the right coronary artery had an eccentric thickening of its wall which reduced the lumen to about 0.1 cm. in diameter. The vessel was completely occluded by clot, beginning 4 cm. from the orifice. The clot extended into the transverse and descending branches. The left coronary artery had a marked diminution in size of lumen to 0.1 cm. for a distance of 0.6 cm. The transverse (circumflex) branch had a lumen only 0.2 cm. in diameter, but was smooth-walled throughout. Microscopic sections through the myo-

cardium of the left ventricle showed extensive areas of infarct necrosis, with an infiltration of moderate numbers of polymorphonuclear neutrophils in the vicinity. Microscopic sections of the right coronary artery through the occluding mass showed eccentric thickening of the vessel wall by an increase in connective tissue, the latter containing scattered islands of vacuolated macrophages. The thickening encroached to only a slight extent on the size of the lumen. Fanning off into the lumen from the surface of the thickening were alternate masses of fibrin, serum and platelets. This clot completely occluded the vessel. In the outer portions of the muscularis and in the tissues about the vessel there were a few scattered lymphocytes and occasional polymorphonuclear neutrophils. The lining surface of the aorta was yellowish white, with slightly elevated yellowish areas in places.

The kidneys weighed 180 gm. each and were negative, except for the microscopic finding of tubules distended with coagulated albumin. The spleen was enlarged, weighing 460 gm. The splenic pulp was rather soft, and gray to purplish gray. It was diffusely infiltrated by round cells, slightly larger than the adult lymphocyte, and with round and often slightly indented nuclei. There were occasional clumps of stem cells. The liver was also enlarged, weighing 2100 gm. Occasional branches of the portal vein were occluded by grayish brown and purplish brown masses of clot.

The marrow of the vertebrae and sternum was gray to greenish gray and slightly translucent. Marrow from the femur was very soft, almost semifluid in places, and varied from yellowish to grayish green. Microscopic sections showed markedly increased cellularity, especially of the vertebral and sternal marrow. The dominant cell was generally round but occasionally elongate or ovoid. The nuclei were round or slightly indented, with the chromatin often greatest near the nuclear margins. Myelocytic and polymorphonuclear eosinophils were scattered about.

Some mesenteric and retroperitoneal lymph nodes appeared slightly enlarged, but microscopically were negative.

A few branches of the pulmonary artery were occluded by clot, apparently of embolic origin.

This patient had carried a mild hypertension for years, but did not live an especially strenuous life. Her parents are living and well, and she was hardly of the group which one might expect to be peculiarly susceptible to terminal vascular disease.

The leukemia had no direct bearing on her death, so far as could be determined. The white blood cell count was not very high, the clot did not consist primarily of white blood cells, and the encroachment on the lumen of the coronary vessels was arteriosclerotic and not due to accumulated masses of leukemic cells. The presence of clots in branches of the portal vein suggests some increased susceptibility to the formation of thrombi but the cause of the susceptibility is not obvious.

3 Conway Street.

I am indebted to Dr. D. L. Lionberger for assistance in the care of the patient and for information from his records.

CASE RECORDS OF THE FAULKNER HOSPITAL

Antemortem and Postmortem Records as Used in Monthly
Clinicopathological Conferences*

Directed by J BEACH HAZARD, M.D

CASE NO 6374

PRESENTATION OF CASE

An Irish American, aged seventy-four years, was admitted because of pain and vomiting

Fifteen hours before admission the patient began to have severe generalized abdominal pain, occurring in spasms at frequent intervals and associated with persistent vomiting. Vomitus at first consisted chiefly of food recently eaten and subsequently of apparently bile-stained fluid. These symptoms continued throughout the night. In the morning the spasms of pain became less, but the patient was aware of a sensation of soreness in the right lower quadrant, which became worse during the three hours previous to admission. Vomiting still occurred occasionally. The patient's bowels had moved several times during the night and once during the morning.

A large left inguinal hernia had been present for many years and had been rather inadequately helped by a truss. Occasionally it would become incarcerated and on several occasions it had been reduced with difficulty. For some years, also, there had been a vague complaint of "stomach trouble," which the patient usually ascribed to his hernia.

Physical examination showed a well-developed and well-nourished man. The temperature was 100°F., pulse rate 96, and respirations 22. The skin and tongue were clear. Examination of the head and neck was negative. The arteries showed a moderate degree of sclerosis, consistent with the patient's age. The lungs were clear. The heart was not enlarged, and no thrills or murmurs were present. The blood pressure was 130 systolic, 76 diastolic. The pulse was rapid, regular and of good quality. Extremities and reflexes were negative. The left external inguinal ring was distinctly dilated, and a definite impulse could be felt. The abdomen was slightly distended and showed distinct tenderness and marked spasm over the entire right lower quadrant, with some tenderness out along the right flank. Rectal examination was negative.

Examination of the blood showed a white-cell count of 17,500 with 88 per cent polymorphonu-

clears, the red-cell count was 4,900,000. Erythrocytes and platelets appeared normal. A blood Hinton was negative. No urinalysis or stool examination was reported.

Laparotomy was performed two hours after admission. The appendix was removed, and a culture taken of the peritoneum, which showed *Staphylococcus aureus*.

For the remainder of the day following the operation the condition of the patient was fairly good. The abdomen remained soft and non-tender. The pulse was of fairly good quality. That night, ten hours after operation, the clinical picture changed entirely. The patient became rather suddenly cyanotic, and the pulse more rapid, the blood pressure dropped to systolic 98, diastolic 70, there were moderate dyspnea and an elevation of temperature to 103.6°F. Cardiac stimulation was given and the patient improved somewhat, although his blood pressure did not rise above 100 systolic, 68 diastolic. The pulse rate was about 130 per minute. In the morning another attack of cyanosis and dyspnea occurred. He was given digifolin, intravenous glucose and caffeine, as well as oxygen, to no avail, and he died twenty hours after admission.

DIFFERENTIAL DIAGNOSIS

DR EDWARD L. YOUNG, JR. First, a few comments about the description of this pain. I have said for a great many years, and still believe, that in the vast majority of cases abdominal pain, whether epigastric, about the umbilicus or generalized, which shifts and localizes in the right lower quadrant, is due to appendicitis. That is, assuming the history can be relied on. I have seen two exceptions: the first, a gangrenous gall bladder presenting in the appendix incision, and the second, a gangrenous epiploic appendix of the cecum. So, assuming this story to be true, the patient is suffering from acute appendicitis. However, let us assume that it is another exception.

It is true that this onset is pretty vicious for acute appendicitis, particularly in a man of seventy-four, because at that age the symptoms are more likely to be atypical. The picture is usually one with vague abdominal symptoms, and when operation is finally done, one is apt to find an advanced stage of the disease. The bowels have moved several times so that the condition is presumably not one with intestinal obstruction, although, of course,

Beginning in October 1937 the clinical meetings at the Faulkner Hospital have been in the form of clinicopathological conferences with paper discussions of cases not previously seen by the discussor. This form of medical exercise originated by Dr. Richard C. Cabot at the Massachusetts General Hospital and at present directed by Dr. Tracy B. Mallory has met with enthusiastic response at the Faulkner Hospital. We are much indebted to Dr. Mallory for his kind advice and assistance in helping us to organize these conferences.

the bowels do move after obstruction, though generally not to this extent. The hernia is thought of, but strangulation should give more definite localization. The fact that the pain came on in spasms means that some hollow viscus is in trouble, and the persistent vomiting suggests either an interference with blood supply, such as a strangulated hernia, or trouble high in the gastrointestinal tract. They did consider trouble with the hernia and apparently had to throw out that diagnosis. The history lacks details about his "stomach trouble," but it certainly did not impress the examiner as being important, nevertheless, we must remember that perforation is often the first symptom of sufficient importance to call attention to an ulcer. It is equally true that a perforation of the duodenum can allow fluid to trickle down the right gutter so that the maximum tenderness is in the right lower quadrant. Is it possible that the history points toward a ruptured gall bladder with bile trickling down the right flank? I believe that is very remote. Gall bladders do rupture, but almost without exception into a walling-off mass of omentum. Gall-bladder disease generally has a degree of chronicity which produces protective adhesions so that free intraperitoneal rupture is uncommon.

What other things have we that are at all likely? Diverticulitis of the sigmoid, for instance, is very unlikely. Pneumonia with intra-abdominal symptoms is ruled out by the examination. After all, one has to take the weight of evidence and act on it. If every case that came to us for diagnosis was a typical story-book picture, there would not be any fun in the practice of medicine. Here it seems to me that the weight of evidence points toward an acute appendicitis. I am basing my diagnosis on the following: generalized abdominal pain shifting to the right lower quadrant, tenderness and spasm, slightly elevated temperature, and high white count with a high percentage of polymorphonuclears. We are told that the appendix was removed.

DR J. BEACH HAZARD: May I interrupt? The same diagnosis was made preoperatively as has been made by Dr. Young. At operation an appendix was removed that at the time looked innocent and later showed healed appendicitis with obliteration. A fibrinopurulent exudate was present about the cecum and extended along the ascending colon toward the subhepatic region.

DR YOUNG: Thank you. That does help because nine times out of ten, a healed appendix is essentially a normal appendix. There is a degree of fibrosis that increases in an appendix as we get older which is a normal process, but it can be pathologic and the pathologist cannot say whether the degree of sclerosis which he finds is actually

due to a pathologic process or merely to a physiologic one. However, in this case I believe the cause of the peritonitis was not acute appendicitis.

The peritonitis was said to be essentially right-sided. There is no evidence of a perforation of the cecum from a solitary ulcer, which, though rare, does occur. I think by a process of exclusion we must say that the patient had a small perforation of the duodenum with irritating fluid going down into the right lower quadrant. I should be interested to know how soon after eating this happened, because the farther away we get from a meal the more likely we are to find that the contents from a perforated stomach or duodenum are sterile. I have not spoken of a perforation secondary to a carcinoma, which we always think of at his age, because malignant disease that has gone far enough to perforate should have given other signs before this. I think the best bet is a peptic ulcer.

The final picture simply concerns which of the causes of death, common to such a picture as this, we have here. I believe that the causes of death following operation can be put into one of five classes: pulmonary embolus, cerebral accident, coronary disease, shock or hemorrhage. Shock may be due to various things—not only surgical shock but overwhelming infection, particularly in the peritoneal cavity. This patient did have *Staphylococcus aureus* in the peritoneal cavity, and I believe the cause of death was peritonitis. Of course, I cannot rule out pulmonary embolus, but death occurred quite soon after operation, nevertheless, it may be the answer. At seventy-four, I suppose that I should think more seriously of a cerebral accident or an acute cardiac accident, but I am betting against them.

DR FRANCIS G. BARNUM: Is there any possibility of acute pancreatitis?

DR YOUNG: Perhaps I should have mentioned it, but I have never seen this disease with a shifting of the symptoms and signs to the right lower quadrant.

A PHYSICIAN: May you not have peritonitis without any obvious cause?

DR YOUNG: That is perfectly true. The only idiopathic types I know of are streptococcus or pneumococcus peritonitis, metastatic from a point outside the peritoneum.

DR HORACE K. SOWLES: I have been able to find on record no cases of so-called idiopathic peritonitis over the age of thirty-two years.

DR CHANNING FROTHINGHAM: Since the patient is so old, why do you not think of some disturbance in the circulation of the mesentery?

DR YOUNG: The pain that is associated with mesenteric thrombosis is more or less a steady pain. I have never seen pain of this type with that sort

of thing. Moreover, in fifteen hours a positive culture should not be obtained from the peritoneal cavity.

DR FROTHINGHAM Too soon?

DR YOUNG Yes

DR BASIL E. BARTON Do you not believe that, where there are cyanosis and dyspnea, pulmonary embolus is indicated rather than peritonitis?

DR YOUNG Not necessarily. I checked up on pulmonary embolus and found that there were as many cases that died of pulmonary embolus without cyanosis as with it and that cyanosis was present where the cause of death was something else so often that I am not using it as being indicative of pulmonary embolus. I believe that this man died of shock from an overwhelming infection of the peritoneum coming from a perforated peptic ulcer.

CLINICAL DIAGNOSES

Perforation of the gall bladder
Acute peritonitis
Peripheral circulatory collapse

DR YOUNG'S DIAGNOSES

Perforated peptic ulcer
Acute peritonitis

ANATOMIC DIAGNOSES

Chronic duodenal ulcer with perforation
Peritonitis, acute, right side of peritoneal cavity
Myocardial fibrosis, left apex
Bronchopneumonia, early
Arteriosclerosis

PATHOLOGICAL DISCUSSION

DR HAZARD Only the right side of the peritoneal cavity evidenced a deposit of fibrin and a purulent exudate. This was most abundant about the gall bladder and duodenum. The appendix stump was intact. The ampulla of the gall bladder was firmly adherent to the superior surface of the duodenum. On opening the latter an ulcer, 2.5 cm in greatest diameter, was found situated about 1.5 cm from the pylorus and immediately adjacent to the region of adherence to the gall bladder. A gross perforation was not evident at first but after fixation and sectioning, a small communication 1 or 2 mm in diameter was found to extend from the lateral portion of the ulcer base through the visceral peritoneum. The gall bladder was negative except for a pericholecystitis. The other finding of interest was an old scar 1.5 cm in diameter, in the apex of the left ventricle. The coronary arteries were patent but presented marked arteriosclerotic changes. A culture of blood from the right ventricle was negative, and one from the exudate in the peritoneal cavity showed *Staphylococcus aureus*.

The extent of the peritonitis did not seem sufficient for this alone to be the cause of death, but with the exception of the scarred myocardium no other important gross anatomic lesion was evident. Histologically an early bronchopneumonia was found but was so slight that it probably did not contribute materially to the patient's exitus. Because of restrictions, the head was not examined. It was felt that the immediate cause of death could be ascribed to circulatory collapse.

CASE 6375

PRESENTATION OF CASE

A Canadian motorman, aged fifty-four years, was admitted because of precordial pain.

The patient had been in fair health until one year before admission at which time he noted a rather insidious onset of precordial pain coming on after exertion, and occasionally after meals. This pain was described as being of a dull oppressive type, rather transitory, and exhibiting no radiation. Coincident with the development of this pain he observed a moderate amount of dyspnea on exertion, and more recently had had a tendency to orthopnea. The pain and dyspnea occasioned the patient no great amount of discomfort, and he worked steadily until three weeks previous to admission at which time the precordial pain became more severe and was accompanied by the onset of rather marked weakness, mild diarrhea and an increase in dyspnea and orthopnea. A cough, which the patient had had for some years became much more marked but was productive of only the whitish mucoid material ordinarily noticed. Two weeks before entry the patient experienced one day of severe and agonizing precordial pain, which radiated down the left arm and through to the left scapula. He had been taking digitalis during the three weeks before entry and had remained in bed for the greater portion of this time. Extensive x-ray studies of the chest, gastrointestinal tract and gall bladder at the office of a roentgenologist had been made a few days before admission. No edema or other signs of congestive failure had been noted. The patient was said to have had a temperature of 102 or 103°F about a week before he came to the hospital.

He was born in Nova Scotia but had lived around Boston for more than thirty-five years. His general health had been good. He had had the usual childhood diseases without apparent complications or sequelae. There was no history of rheumatic fever, scarlet fever, diphtheria, typhoid fever or syphilis. He had had an appendectomy performed seven years previous to admission. For many years he had had 'bronchit

trouble," which was characterized by a chronic cough productive of whitish mucoid phlegm. His past history was otherwise essentially negative prior to the present illness. He had lost from 10 to 15 lb. in the year previous to admission.

There was no history of familial disease. The patient's father died of "senility" at eighty-eight years and his mother of "apoplexy." He had been married for seventeen years, and his wife was living and well. There were no children.

Physical examination showed a well-developed and nourished man lying comfortably in bed, he was somewhat orthopneic and had a tired, worn-out appearance. One observer thought there was an icteric tint to the sclerae. He was slightly confused and unable to concentrate well in conversation. Thought sequences were distorted. There was no tremor of the extended fingers. The pupils were slightly irregular and showed a moderate arcus senilis. They reacted to light and accommodation. The fundi revealed moderate arteriosclerotic changes, the disks showed definite cupping. Sinuses, nostrils, mouth and teeth were not remarkable. There was no generalized enlargement of the lymph nodes. The supracardiac diameter was 7 cm. The heart was enlarged to the left as far as the anterior axillary line, and there was questionable enlargement to the right. The heart action was slow, but the rhythm was grossly irregular. The heart sounds were very distant and of poor quality. No murmurs could be heard. The peripheral vessels, especially the radial arteries, were arteriosclerotic. The pulses were equal but of poor quality. The blood pressure was 110 systolic, 46 diastolic, and a later reading was 110 systolic, and 70 diastolic. The percussion note over the lung fields was resonant except for a small area at the angle of the left scapula where there was bronchial breathing with increased whispered and spoken voice. A second observer did not confirm this. Elsewhere the breath and voice sounds were normal. A few moist rales could be heard at both lung bases. The abdomen was fully relaxed and revealed no masses, spasm or tenderness. There was an incisional hernia at the lateral border of the right rectus muscle in the lower quadrant. The liver and spleen were not palpable. Knee jerks were diminished but were about equal. The Babinski sign was equivocal, Gordon and Oppenheim signs were negative. There was no patellar or ankle clonus. Vibration sense was normal. Rectal examination was negative. The prostate was mildly and symmetrically enlarged but was of average consistence.

On admission the temperature was 98.6°F., the pulse 52 and the respirations 32. The urine showed a slightest possible trace of albumin and occasional

erythrocytes but no white blood cells or casts, a second urinalysis was negative. The specific gravities were 1.017 and 1.022. The white blood-cell count was 15,800, with 83 per cent polymorphonuclears, 11 per cent lymphocytes and 6 per cent young polymorphonuclears. The red-blood-cell count was 5,100,000, with 99 per cent hemoglobin (Sahli). Red blood cells and platelets appeared normal. Stool examination was negative. A blood Hinton test was negative. The blood nonprotein nitrogen was 41 mg. per cent.

A six-foot chest plate showed the transverse diameter of the heart to be 17.5 cm. Internal diameter of chest was 28.8 cm. The great vessels measured 6.0 cm. The heart was enlarged to the right and left, and there were pulsations of normal intensity and rhythm. The esophagus was displaced slightly to the right and posteriorly. There was a small amount of fluid in the right chest, which partially obscured the costophrenic angle. The x-ray impression was cardiac enlargement with no evidence of hydropericardium.

An electrocardiogram taken on the day of admission showed auricular fibrillation, ventricular complexes that were not remarkable, two ventricular extrasystoles and no evidence of overdigitalization.

The patient's course in the hospital was uneventful although he seemed to improve. After two days his temperature rose to 100°F. every afternoon. The pulse varied between 60 and 80 but rose to 100 on the fifth day, respirations were between 20 and 25. Five days after admission, while sleeping, he suddenly became cyanotic, gasped several times and died.

DIFFERENTIAL DIAGNOSIS

DR WILLIAM R. OHLER. We are first interested in an analysis of the patient's history. This is a very interesting case, and I think that I can begin with a little different approach.

First, there is one possibly important point in the family history. It states that the mother died of "apoplexy," but no mention is made of the mother's age at the time of death. It is possible that this man may have started out with a hereditary factor insofar as hypertension is concerned.

Let us next consider one or two facts about the patient's past history. There was no history of rheumatic fever but there was a history of bronchial trouble for a good many years. This may be of importance when we come to take up some of the points in the present illness.

Coming to the present illness, we have a fifty-four-year-old white man who had been in reasonably good health and able to carry on his work until a short time before his admission to the hospital. However, about a year before

his admission he began to note the onset of precordial pain which bore a very definite relation to exertion. We note that the precordial pain was supplemented a little later by dyspnea, which as time went on became severe enough to cause orthopnea. Thus we have a pretty good picture of coronary disease, probably sclerotic in nature, with evidence of beginning myocardial failure.

About two weeks prior to admission the patient had a rather severe attack of precordial pain, very sharp in nature, which radiated into the neck, the region of the left scapula and down the left arm. This certainly sounds like an attack of coronary occlusion. The cough which had been present for some years then became a little bit more marked. Also, the record states that the patient had a temperature of 102 or 103°F for some time prior to entrance to the hospital. This would be consistent with acute coronary disease or a mild pulmonary infection superimposed on the chronic bronchitis, or both.

The statement that the patient was somewhat confused and unable to concentrate well in conversation and reading, I am unable to explain other than to say that patients with congestive heart failure are very frequently mildly psychotic. The fundi revealed moderate arteriosclerosis. Then there is a note here that the disks showed definite cupping. I am not sure that that indicates anything more than physiologic cupping. There is no evidence of disturbance in vision, no headaches or no mention of anything suggesting glaucoma.

Turning for a moment to the examination of the heart, we find that it was enlarged, the rhythm was grossly irregular, suggesting auricular fibrillation. There is no mention of auricular fibrillation in this patient's history prior to admission to the hospital. If he had no auricular fibrillation prior to the onset of his acute attack of cardiac pain, then it is reasonable to suppose that the auricular fibrillation came after that. On the other hand, if he had auricular fibrillation prior to the onset of the attack, that makes one wonder as to whether he had coronary disease, because people with auricular fibrillation, by and large, do not get coronary attacks anywhere near so frequently as people without it. They may develop auricular fibrillation following attacks. I am assuming that this individual developed auricular fibrillation following his attack of cardiac pain.

He had a very low blood pressure and a relatively high pulse pressure. This is consistent with coronary disease. We know nothing about this patient's blood pressure prior to his present illness, but on the basis of his family history it is fair to assume that he had hypertension before the onset of cardiac symptoms.

There is no evidence of edema and no evidence of an enlarged liver, this suggests that, despite the story of right-sided enlargement, there was no right-sided failure. Such evidence of failure as we have points to the left side, which is consistent with hypertensive heart disease. This man ran a temperature while he was in the hospital, and if he had had an acute coronary occlusion two weeks before admission, this is a little bit long for the temperature to persist. Nevertheless, I have no other explanation unless he had a lesion in the chest of infectious origin. Subsequent laboratory work which was done in the hospital, including x-rays and electrocardiograms, only lend support to the picture which we are attempting to develop. He had an enlarged heart. He had some moist rales suggesting a little fluid at the lung bases. He had an electrocardiogram which showed auricular fibrillation.

This individual did pretty well and then died very suddenly five days after admission. He died during the night, and his death was associated with cyanosis. No mention is made in the record concerning the rapidity of death. It is assumed that death was extremely sudden and that no time element could be stated. That is perhaps important in trying to figure just what caused death. Cardiac deaths can be very sudden, deaths from embolus are likely to be not so sudden. Generally, the shortest period of death from embolus is not less than ten minutes.

In summarizing the situation, we have an individual who gives a pretty good story of coronary sclerosis, with increasing evidence of myocardial weakness—a story that suggests an attack of coronary occlusion roughly about three weeks before death, a progressively downward course since then, insofar as evidence of cardiac pain was concerned, a persistence in temperature, and then sudden exitus. If one assumes that he had coronary occlusion, then one can assume that his death was due either to mural thrombosis or to rupture of the ventricular wall at the site of a very large infarct. I am inclined to feel that this individual had hypertensive heart disease with an enlarged heart, coronary sclerosis and coronary occlusion complicated by a large infarct in the heart wall, which ruptured at the time of death. The fact that cyanosis was noted does not help us one way or the other because you can have cyanosis associated either with a rupture of the ventricular wall or with a large pulmonary embolus.

If this individual had auricular fibrillation prior to the onset of this rather sharp pain, one is entitled to say something in favor of another possible diagnosis. If you read over the record you will note that, in addition to the x-ray showing

that the heart was enlarged, there is some suggestion by x-ray that the esophagus was deviated somewhat to the right. Apparently no pulsation was felt. It is perfectly possible that an individual with a dissecting aneurysm might give a story somewhat similar to this. There was precordial pain to begin with, terminating in an acute episode at the end. I do not believe that I can rule out the possibility of a ruptured dissecting aneurysm as the cause of death. Nevertheless, on the weight of evidence, I am in favor of my former diagnosis.

DR JAMES A. HALSTED: I saw the patient in the ward and felt that he probably had coronary thrombosis, but because of the high white count, the elevated temperature and some dulness in one side of his chest, I thought that he might have a pulmonary infarct.

CLINICAL DIAGNOSES

Arteriosclerosis, general
Infarction of myocardium, due to arteriosclerotic coronary thrombosis
Rupture of heart due to infarction

DR. OHLER'S DIAGNOSES

Hypertensive heart disease
Coronary arteriosclerosis
Coronary occlusion with ruptured ventricular infarct

ANATOMIC DIAGNOSES

Cardiac infarction, old, due to arteriosclerosis and thrombosis of the anterior descending branch of the left coronary artery
Rupture of old myocardial infarct
Hemopericardium
Mural thrombi, left ventricle
Hydrothorax, partial, bilateral
Chronic bronchitis

PATHOLOGICAL DISCUSSION

DR J. BEACH HAZARD: On opening the pericardium a layer of adherent fibrin was encountered which when disrupted revealed a pericardial cavity filled with blood. A thin layer of shaggy, blood-stained material covered much of the pericardial surface. The heart was enlarged, and the apex of the left ventricle bulged outward. At the lateral, inferior margin of this bulging portion was an irregular tear, 1.8 cm. in length, which communi-

cated with the left ventricle. The wall in this vicinity was thinned to 1 or 2 mm. in thickness, and the tissue on either side was white and tough. This white tissue, with occasional rare muscle bundles, formed most of the wall of the apex. The lining surface presented firmly adherent mural thrombi. The anterior descending branch of the left coronary artery at a point 1.2 cm. from its origin was occluded by white and brownish-white tissue, and its wall was partly calcified. Histologically, sections through the apex revealed dense connective tissue and occasional bundles of muscle, but no region of acute infarction. A zone of polymorphonuclear infiltration was present near the outer aspect of the line of rupture. The fibrin on the epicardial surface was partly organized. The infarct was old, and it does not seem possible it could have been the cause of the attack two weeks before death. This might have been associated with a beginning leak into the pericardial sac, as the layer of fibrin on the pericardium could be estimated at somewhat near that age.

The heart was markedly enlarged, chiefly due to dilatation of the left ventricle.

DR. OHLER: By an old infarct you mean it happened when?

DR. HAZARD: I do not believe it could possibly have happened under a month. The story of the attack of pain and of fever is just about two weeks before death. The infarct is much older than that. As a bare second possibility, the temperature might be accounted for by a respiratory infection as there was a marked chronic bronchitis.

DR. HALSTED: The history was inaccurate, as I remember it. Is it possible that the pain might have occurred a month before instead of two weeks before death?

DR. RAYMOND CLAPP: No, this acute episode had occurred about two weeks previously as attested to by his wife.

DR. CHANNING FROTHINGHAM: This case emphasizes the importance of making the diagnosis of coronary occlusion promptly because other diagnostic procedures such as were carried out on this patient necessitate appreciable exertion, which is of course contraindicated in the early days of coronary occlusion. Furthermore, if coronary occlusion is suspected it would be well to postpone for a time diagnostic procedures for the diagnosis of conditions which do not need immediate treatment.

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTEMORTEM AND POSTMORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT, M.D.

TRACY B. MALLORY, M.D., *Editor*

CASE 24041

PRESENTATION OF CASE

A fifty-six-year-old, white, single, Canadian-born female entered the hospital with a diagnosis of ischio-rectal abscess of three weeks' duration.

Seven weeks before entry she had a gastrointestinal upset, with fairly marked diarrhea and the passage of small amounts of bright-red blood by rectum. During the succeeding weeks she continued to have intermittent attacks of diarrhea, but they slowly lessened in severity until at the time of entry they gave her relatively little trouble. Three weeks before entry she noticed superficial tenderness on the left side of her rectum. This tenderness gradually increased and became much more severe in the last week before entry. In spite of poulticing, the pain finally became unbearable. She consulted her physician, who lanced an abscess near the rectum and sent her to this hospital.

The past and family histories were essentially negative.

Physical examination revealed a fairly well-developed and nourished woman lying in bed. The chest and abdomen were negative. The blood pressure was 130 systolic, 70 diastolic. Just to the left of the rectum was a large, bulging, fluctuant ischio-rectal abscess.

The temperature was 98°F, the pulse 85. The respirations were 20.

Examination of the urine was negative.

On the day of entry the ischio-rectal abscess was incised and drained, and an anal fistula repaired. The following day the temperature rose to 103°F, and she appeared very ill. During the next two days her condition improved somewhat, but on the fifth day she began to complain of generalized soreness and developed increasing distention with some vomiting. Examination revealed moderate tenderness of the abdomen, more marked in the left epigastric region, with hyperactive peristalsis. No masses could be made out. During the next three days these symptoms became more pronounced, and an x-ray on the ninth hospital day showed marked gaseous distention of the stomach and dilatation of the jejunum. There was no

visible gas in the colon. At that time the blood showed a red-cell count of 3,930,000 with 70 per cent hemoglobin. The white-cell count was 10,600, 77 per cent polymorphonuclears. The nonprotein nitrogen of the blood serum was 50 mg per cent, the protein 5.6 gm per cent, and the chlorides equivalent to 101 cc of N/10 sodium chloride. An exploratory laparotomy was done, and a large localized abscess was found between the ileum and cecum. On aspirating the pus a large perforation was discovered in the cecum, through which fecal matter oozed into the abscess cavity. A large soft rubber tube was sutured into the perforation and two cigarette drains placed down in the abscess cavity. A Witzel ileostomy was done. On the following day the temperature was 102°F, and the blood showed a white-cell count of 17,800. She was quite lethargic and almost in a moribund condition. Wangensteen suction was instituted, and during the next three days she seemed to improve. On the eleventh day, three days after the laparotomy, her temperature was almost normal, the white-cell count 10,700, with 95 per cent polymorphonuclears, the nonprotein nitrogen 44 mg per cent, the protein 4.8 gm per cent, and the chlorides equivalent to 107 cc N/10 sodium chloride. Two days later she was found dead in bed. An hour before death she had seemed to be in fairly good condition.

DIFFERENTIAL DIAGNOSIS

DR. LELAND S. MCKITTRICK. So far as I am concerned all the laboratory work can be put aside as of no help in arriving at a diagnosis. We have then a fifty-six-year-old woman who apparently was well until seven weeks before she came in, when she had an attack of bloody diarrhea which persisted for at least three weeks and apparently had not entirely subsided, because the statement is that it gave her relatively little trouble at the time of entry. Then she developed an ischio-rectal abscess and came into the hospital. The ischio-rectal abscess was drained, and instead of being better she became a very sick patient, with a temperature of 103°F. It seems to me that that probably means the flaring up of a pre-existing process.

She goes on with abdominal distention and x-ray evidence of a dilated stomach and jejunum. Then she was operated upon again, an abscess was found between the terminal ileum and the cecum, and a fistulous opening was demonstrated in the cecum.

Perhaps this would be a good time for Dr. Holmes to show the x-rays, so we can have all the cards on the table before we proceed.

X-RAY INTERPRETATION

DR. GEORGE W. HOLMES. I can only point out what is already mentioned in the report. The

dilated stomach is evident, and here are the loops of dilated small bowel. We can be reasonably certain that they are small bowel. There seems to be an unusual amount of density in the lower part of the pelvis, which may be apparent only because the films are portable and underexposed. There may be some fluid present. I do not see anything that will give us any real help. In the text it says that there is no visible gas in the large bowel. I think that might be questioned, although it is more likely to be correct.

DIFFERENTIAL DIAGNOSIS (CONTINUED)

DR. McKITTRICK: Why do we not put the x-rays with the other laboratory work and say that they are of no help?

DR. HOLMES: The x-rays do show definite evidence of obstruction.

DR. McKITTRICK: Yes, but I do not think that that is the cause of her trouble. I think we have a right to assume that she has a process involving the entire colon and that she has ulcerations in the colon, one of which has gone through the rectum and formed an ischio-rectal abscess, the other through the cecum resulting in the abscess found at operation.

If, then, we assume the presence of ulcerations in the cecum and rectum, I believe we may feel fairly confident that the intervening bowel is involved in a similar though less marked process. If this is so, then we have to make a diagnosis of some form of ulcerative colitis. The two types of the disease that one needs to consider are so-called chronic idiopathic ulcerative colitis and amebic dysentery. We have no evidence pointing to amebic dysentery, and we have nothing to prove that she did not have idiopathic ulcerative colitis. When the abscess between the terminal ileum and cecum was first mentioned, of course the first thing that came to mind besides appendicitis was a regional ileitis of some type, but I do not believe we have any reason for more than mentioning such a process.

I feel quite stupid about the whole thing, but either the diagnosis is easy or I am entirely wrong. I believe she had idiopathic ulcerative colitis with perforation of the cecum and erosion through the rectum. If that is the diagnosis, why did she die? I think she was probably sicker than the final note would lead one to suspect. The note says "An hour before death she had seemed to be in fairly good condition." The most common cause of finding a patient of her age dead in bed after operation is pulmonary embolism, and I suspect that she may have had it, it is quite possible, however, that she did not. She had a localized peritonitis, and that may have become generalized. I shall

only say that she died of ulcerative colitis with perforation.

CLINICAL DISCUSSION

DR. RICHARD H. SWEET: There are one or two clinical aspects of this case that are not in the record but are of interest. I think Dr. McKittrick is to be complimented on making the correct diagnosis. I did not think it was so easy when I first saw her with the ischio-rectal abscess. She did not have constant diarrhea, but she had had two months of intermittent attacks. On opening the ischio-rectal abscess there was a sizable ulcer in the rectum, not an ordinary fistulous opening. It is so unusual to find the internal opening that I was surprised to find an ulcer there. She was abnormally sick after draining the abscess. About three or four days later she commenced to have massive hemorrhages, which are not mentioned in the record. She bled profusely from the rectum and for a period of about a week had intense lower abdominal pain, in the meantime becoming gradually very distended, I was puzzled because I did not think she had obstruction of the large intestine. I thought the abdominal film demonstrated quite conclusively that she had small-bowel obstruction and dilatation. Dr. Allen saw her with me that night, and I operated on her with a pre-operative diagnosis of obstruction of the small intestine, the cause of which was unknown. She was a little tender in the right lower quadrant. I made my incision where one would ordinarily for an ileostomy and came down right over an abscess. The thing that made the diagnosis difficult for me was that the colon was not dilated in spite of the fact that it was perforated. I thought she must have ulcerative colitis, since perforation had occurred. There was a definite abscess, and several loops of small intestine were adherent to it. There were dilated loops above this point and collapsed loops below. We drained the abscess and put a tube in the cecum and one in the ileum. The surprising thing was that she lived for three days after that, but she was in very poor condition before she died.

CLINICAL DIAGNOSES

Ischio-rectal abscess
Perforated cecum
Peritonitis

DR. McKITTRICK'S DIAGNOSIS

Idiopathic ulcerative colitis with local and possibly general peritonitis

ANATOMIC DIAGNOSES

Ulcerative colitis with perforation of the cecum
Peritonitis, acute, localized

Cecostomy
 Ileostomy
 Ischiorectal abscess with drainage incision
 Fatty vacuolization of the liver
 Infarcts of the right kidney, healed and recent
 Pulmonary edema and hyperemia
 Hydrothorax, bilateral
 Ascites
 Arteriosclerosis of the coronary arteries and the aorta
 Operative scar supracervical hysterectomy and bilateral salpingo-oophorectomy

PATHOLOGICAL DISCUSSION

DR. BENJAMIN CASTLEMAN The autopsy showed just about what Dr McKittrick predicted. There was not, however, a general infection of the peritoneal cavity. The peritonitis was localized to the cecal region. On opening the cecum we found a number of acute ulcerations, one of which had perforated. There were ulcerations throughout the whole large bowel, but very few in the sigmoid and descending colon and just an occasional small one farther down. We were unable to find any perforation of the rectum. This case is unusual because in this disease the most severe lesions as a rule are in the sigmoid and rectum and gradually become smaller or not apparent in the cecum. Here, it was just the reverse. We were unable to account for her death. There was no embolus and no coronary thrombosis. We did not examine her head, but I doubt whether we would have been able to find anything there.

DR. SWEET She was never well enough for us to do a proctoscopic examination.

DR. CASTLEMAN How often do you see an ischiorectal abscess as the first indication of ulcerative colitis?

DR. MCKITTRICK We get off on the wrong foot in these cases because when we see someone with an abscess, that stops the investigation. They are common, and we do not think too much about them. Anyone who has bloody diarrhea for three or four weeks has something the matter with him. I have been on service enough to know that when someone with a common disease like ischiorectal abscess is presented to you, the past history of bloody diarrhea is apt to be minimized and put in the background with the result that nothing is said about it and not much attention is given to it. I think it is fair to say that some type of ulceration through the rectum into the vagina or into the ischiorectal area is not uncommon in the course of the more acute cases of ulcerative colitis.

The hemorrhage which Dr Sweet speaks about interests me because one gets such massive hem-

orrhages in patients who have large deeply penetrating ulcers overlying the mesenteric border. In what little experience I have had with this most extraordinary disease, the cases with massive hemorrhage are very apt to be fatal.

CASE 24042

PRESENTATION OF CASE

First Admission A sixty-three-year-old Irish club steward entered the hospital with the complaint of hematuria of four years' duration.

Four years before entry he began having hematuria, which occurred about once every three months and lasted about a day. Two and a half years before entry cystoscopy revealed a large sessile growth and four small papillomatous growths at the base of the bladder, all of which were deeply cauterized by diathermy. At intervals up to the time of entry diathermy cauterization was repeated for recurrent growths. During the three months before entry he was essentially symptom-free except for increase in his nocturia to three times a night and occasional sharp, fleeting pain on urination. During the week before entry this pain increased in severity. He never had any retention, incontinence or difficulty in starting the stream.

His past and family histories were essentially negative. He had had no significant weight loss in the five years before entry.

Physical examination revealed a rather emaciated man in no apparent discomfort. The teeth were carious. There was an empyema scar on the lower right chest posteriorly but the lungs were essentially negative except for slight dullness at the right base. The blood pressure was 160 systolic, 90 diastolic. Rectal examination was negative.

The temperature was 98.6°F, the pulse 62. The respirations were 20.

The urine had a specific gravity of 1.020 and contained the slightest possible trace of albumin. A phenolsulfonephthalein test of renal function gave 40 per cent excretion in an hour and a total of 50 per cent in two hours. The nonprotein nitrogen of the blood serum was 35 mg per cent.

Cystoscopy revealed a papillary growth on the left side of the bladder involving the orifice and extending from 12 o'clock to about 5 o'clock. On the fourth hospital day a suprapubic cystotomy was done and the growth thoroughly treated with diathermy. He was discharged on the sixteenth hospital day.

Second Admission (two years later) Repeated cystoscopic examinations during the next year were negative, and up to three weeks before re-entry he was entirely symptom-free, with nocturia only once a night. At this time he again had hematuria which occurred twice a week until entry.

Physical examination was essentially negative except for slight enlargement of the prostate

The temperature was 98.6°F., the pulse 80 The respirations were 20

The urine showed a specific gravity of 1.024 and contained a slight trace of albumin with rare white blood cells in the sediment A phenolsulfonephthalein test of renal function showed 70 per cent excretion in two hours The nonprotein nitrogen of the blood serum was 32 mg per cent, and a blood Hinton was negative

X-rays of the abdomen were essentially negative

Cystoscopy revealed a small, white, solid looking tumor about the size of a pea on the posterior upper right wall of the bladder, which was cauterized Bilateral vasectomy was also done He was discharged on the nineteenth day

Third Admission (seven years later) He was seen at intervals in the Out Patient Department without evidence of recurrence until a month before entry, when he again had hematuria His general health had been good except for slight dyspnea on exertion

Physical examination showed marked peripheral arteriosclerosis, with a loud apical systolic heart murmur and a blood pressure of 200 systolic, 100 diastolic

The temperature was 98°F., the pulse 55 The respirations were 20

The urine showed a large trace of albumin and contained many red blood cells The blood showed a red-cell count of 4,960,000 with a hemoglobin of 80 per cent, and a white-cell count of 11,500 The nonprotein nitrogen of the blood was 39 mg per cent

Cystoscopy revealed a good-sized, translucent, papillary growth just inside the bladder outlet on the left at 5 o'clock The growth was thoroughly coagulated, and a few strips of tissue were removed from the median bar of the prostate, which on pathological examination showed fibrosis and chronic inflammation He was discharged on the tenth day

Final Admission (eight months later) Four months after discharge, while exerting himself strenuously, he suddenly coughed up two mouthfuls of bright-red blood This incident was unaccompanied by other symptoms Cystoscopy was done shortly afterward and showed no evidence of recurrence About a month later, three months before re-entry, he began to notice slight swelling of his ankles, which disappeared at night Two months before entry he discovered that he had gained a few pounds in weight and that the swelling of his ankles was more pronounced and failed to regress at night He also noticed that his abdomen was becoming more protuberant, and he

began to lose his appetite Two weeks before entry he entered an outside hospital, where a barium enema was reported to be negative By that time the swelling of his legs had reached to his knees, and the distention of his abdomen was very uncomfortable The drinking of fluids caused considerable abdominal discomfort, and his bowels, which had always been regular, became constipated so that he had to take laxatives He had no cardiorespiratory symptoms, vomiting or abdominal pain He had never had hematemesis, melena or jaundice, and he drank no alcoholic beverages

Physical examination revealed an emaciated man in some discomfort The retinæ showed moderate arteriovenous nicking The heart was slightly enlarged to the left, and there was a soft, blowing systolic murmur at the apex There was an intermittent arrhythmia, and the sounds were somewhat distant The blood pressure was 184 systolic, 98 diastolic The lungs showed slight dullness at the left base with diminished breath and voice sounds The abdomen was moderately distended, and shifting dullness and a fluid wave could be detected The liver dullness was thought to extend 2 cm below the costal margin The legs showed pitting edema up to but not including the knees The rectal examination was negative except for moderate symmetrical enlargement of the prostate

The temperature was 98.6°F., the pulse 75 The respirations were 20

The urine examination was negative except for 8 to 10 white cells per high-power field and rare red cells in the sediment The blood showed a red cell count of 3,440,000 with a hemoglobin of 65 per cent The white-cell count was 5300, 58 per cent polymorphonuclears A guaiac test on the stool was negative The nonprotein nitrogen of the blood was 40 mg per cent, and the vital capacity of the lungs was 2500 cc. An x-ray of the chest showed prominence of the heart in the region of the left ventricle and a very tortuous, dilated aorta with marked calcification of the aortic knob The right diaphragm was slightly high, respiratory motions were normal, and there was no evidence of pulmonary metastases An x-ray of the pelvis showed marked arteriosclerosis of the pelvic and femoral vessels with no evidence of metastases

Catheterization produced only 60 cc of residual urine, and cystoscopy revealed no evidence of recurrence of tumor of the bladder Before cystoscopy he was given ¼ gr morphine sulfate and 1/150 gr scopolamine subcutaneously When he returned to the ward he was extremely stuporous, with a respiratory rate of 6 He was given caffeine subcutaneously and coramine intravenously with-

out visible improvement. Finally he was given a large dose of caffeine sodiobenzoate intravenously, which produced rapid and dramatic recovery. The following day his respiratory rate was 12. On that day he vomited coffee-grounds material which gave a 2+ guaiac test.

On the seventh hospital day an abdominal paracentesis yielded 3000 cc of clear, light yellow fluid. The fluid had a specific gravity of 1.009, contained 1.1 gm per cent protein and 9000 red cells and 200 white cells per cu mm. No tumor cells were found. On that day the guaiac test on the stool was 3+. On the following day an electrocardiogram showed slight left axis deviation, low T₁, T₂ and T₄, flat T₃ and slurred R₁, R₂ and R₃. A Takata-Ara test was positive. In spite of digitalization and injections of salyrgan, he continued to accumulate fluid, and on the tenth day 3000 cc was again removed from the abdomen. At that time it was noticed that his skin was slightly icteric, and the van den Bergh was 4.05 mg per cent, direct. The nonprotein nitrogen of the blood was 47 mg per cent. The icterus gradually became more pronounced, he became progressively weaker and gradually went into a semistuporous condition. On the seventeenth day he had intermittent spasms of abdominal pain and shortly afterward vomited about 90 cc of bright-red blood. A few hours later he passed some blood by rectum. The following day he died. At no time was the jaundice very marked.

DIFFERENTIAL DIAGNOSIS

DR. JOHN H. TALBOTT: This is the story of a sixty-three-year-old Irish club steward who was seen in the clinic and admitted to the hospital on several occasions for hematuria, presumably caused by a bladder tumor. Most bladder tumors are benign, but they must be watched with great care lest they become malignant. The description of one of the tumors, as given in the history at the first admission, suggests cancer. Since most tumors which become carcinomatous show evidence of this by becoming invasive at the base, it is worth noting that at a previous cystoscopy a large sessile growth was seen.

The history states that four months before his final admission the patient coughed up two mouthfuls of bright-red blood. If this statement were true, the most likely explanation of such a hemoptysis, in the absence of any severe cardiac symptoms, would be pulmonary tuberculosis or a pulmonary tumor. In view of the rest of the story, however, I do not believe that the patient coughed up the blood, but rather that he vomited it and that it came from the stomach or the esophagus. The statement that the patient never drank any al-

cohol must be accepted with reservations, he was a club steward and at least had the opportunity to take alcohol if he desired it.

The patient had dyspnea on exertion, which suggests a poorly functioning heart and vascular system, and on physical examination there was an elevation of the blood pressure with marked peripheral arteriosclerosis. With this evidence I think we can make a diagnosis of generalized arteriosclerosis and say that he probably had some sclerosis of the vessels of his heart. I cannot go farther than this, and I do not believe that the peripheral edema was of cardiac origin. The important thing to decide is whether this man had carcinoma or whether he had cirrhosis of the liver. He had edema of the legs which extended up to the knees, as well as an accumulation of fluid in his abdominal cavity. The specific gravity of the fluid was 1.009 with 1.1 gm per cent protein and about 9000 red cells per cu mm. This is consistent with a transudate and quite characteristic of that obtained in patients with cirrhosis of the liver. The fact that there were some red cells should not bias us in favor of an exudate from carcinomatosis.

In addition to cirrhosis of the liver and cardiac decompensation the other most common cause of peripheral edema is renal insufficiency. I do not believe, however, that this patient had any fulminating renal lesion. He probably had nothing more than some sclerosis of the renal vessels which accompanied the generalized arteriosclerosis. The specific gravity of the urine was high, and the nonprotein nitrogen of the blood was only slightly elevated above normal.

I think that the accumulation of fluid came from liver insufficiency, and our next decision is whether it was a primary cirrhosis of the liver or a secondary involvement from a metastatic carcinoma. This patient had been treated over a period of twelve years for a recurring tumor, but cystoscopy at the last admission showed no evidence of recurrence. Therefore I do not see how we can make a diagnosis of benign tumor of the bladder, eventually becoming malignant and metastasizing. At some time or other we would have had obvious evidence of cancer if this tumor had been anything but a benign growth. If this liver insufficiency was not caused by metastasis from a carcinoma elsewhere, the other likely possibility is a primary cirrhosis. The history states that this patient did not consume alcoholic beverages, and if he did not have an alcoholic cirrhosis, it is possible that he was suffering from an idiopathic cirrhosis. There is no evidence from the history of long-standing biliary-tract disease, and I think we can dismiss the question of a biliary cirrhosis. Rare forms, such as syphilis of the liver,

hemochromatosis and thrombosis of the portal vein, can likewise be dismissed

The question of cancer seems to be the specter in this case, and I believe we should bring up the question of a primary liver cancer superimposed on a cirrhosis. The clinical picture is certainly consistent with the diagnosis of cancer. The slight jaundice, which was never marked, is in favor of a primary cirrhosis of the liver. If he had metastatic involvement of the liver sufficient to give ascites his jaundice should have been much deeper.

I think that the cause of death was cholemia and hemorrhage. The rectal bleeding is a little disturbing, I confess, and I have not satisfactorily explained it. The hematemesis which was observed terminally could be accounted for by bleeding from varices of the esophagus. The fact that the spleen was not felt is against the diagnosis of cirrhosis, but a slight enlargement of the spleen might have been overlooked.

In conclusion, I believe this patient was suffering from generalized arteriosclerosis, idiopathic cirrhosis of the liver and possibly a cancer which was primary neither in the bladder nor in the prostate, but possibly in the liver.

DR. TRACY B. MALLORY: There was one point in the record which Dr. Talbott did not comment on. That was the very marked reaction to $\frac{1}{4}$ gr morphine sulfate. I have a recollection of giving morphine on one occasion to a patient with cirrhosis of the liver and of having the respirations stay below 10 for three successive days. Some of the house officers tell me that they too have noted marked reactions to morphine in cases of cirrhosis, and I wonder if that may not be regarded as an additional point in favor of cirrhosis in this case.

CLINICAL DIAGNOSES

Arteriosclerotic and hypertensive heart disease
Bladder tumor with metastases to the liver and peritoneum?

Cirrhosis of the liver?
Peritonitis?

DR. TALBOTT'S DIAGNOSES

Idiopathic cirrhosis of the liver
Arteriosclerosis
Primary carcinoma of the liver?

ANATOMIC DIAGNOSES

Cirrhosis of the liver, toxic
Ascites
Duodenal ulcer, chronic
Icterus, slight
Arteriosclerotic heart disease, slight
Arteriosclerosis, aortic, coronary and cerebral
Cholecystitis, chronic
Cholelithiasis
Nephritis, chronic vascular, bilateral.
Operative scars: empyema drainage, right chest, cystotomy

PATHOLOGICAL DISCUSSION

DR. MALLORY: We did find a marked atrophic cirrhosis. The liver weighed only 750 gm. It certainly could never have been felt. It was very granular. It did not show any fatty infiltration or hyaline degeneration that would enable us to identify it as alcoholic cirrhosis. I think we have to be content with saying that it was idiopathic or post-atrophic, which is almost the same thing. He had no cancer. The bladder was clean. These papillary tumors of the bladder histologically are almost always benign, but from the clinical point of view they usually behave as if they were carcinomatous. I feel quite hopeless in trying to guess whether one of these tumors is going to recur. In my experience no matter how benign they look they almost always come back, but here with no evidence of recurrence after fifteen years, I think we can say the lesion was cured.

The terminal event was hemorrhage which did not come from varices but from a large duodenal ulcer.

NATIONAL SOCIAL HYGIENE DAY

FEBRUARY 2 will be observed throughout the nation as the second annual National Social Hygiene Day. February 3 was so observed last year. On the present occasion primary importance will be placed upon plans for furthering the national effort to stamp out syphilis, so ably sponsored and initiated by Dr. Parran in his National Conference in Washington in 1936. Since that memorable event, only those in position to know realize to what extent the public has accepted the leadership offered for accomplishing this end, to what degree plans are already laid for future activity, and what definite achievements can already be pointed to with pride. Soon these facts will be apparent to all. In Massachusetts, the State Department of Public Health, the Committee on Postgraduate Instruction of the Massachusetts Medical Society and

the Massachusetts Society for Social Hygiene have effectively joined forces for furthering this end.

Social hygiene work in Massachusetts is rapidly becoming well organized. The current activities are scheduled to cover a period of time both preceding and following February 2. On January 10 there was a thirty-minute broadcast on "Facing the Facts in the Control of Gonorrhea and Syphilis", on January 19 there was one on "Gonorrhea". On January 20, at Ford Hall, Dr. Stanley H. Osborn, commissioner of health of Connecticut, and Dr. Nels A. Nelson, of the Massachusetts Department of Public Health, discussed compulsory tests for syphilis before marriage. On February 2, Dr. Nelson will speak over station WORL in the morning and over a national hook-up from station WEEI in the evening.

The local social hygiene groups of Pittsfield, Holyoke, Springfield, Fitchburg and Cambridge are all planning meetings on National Social Hygiene Day in order to increase the interest and co-operation of the citizens in those communities.

The State Federation of Women's Clubs has taken up the control of syphilis for its health program. Under the able direction of Mrs. William T. Hanson, chairman of the Public Health Division, much of the radio publicity has been arranged, in addition to direction of activities among the local clubs.

The Social Hygiene Committee of the Boston Health League has assumed responsibility for several publicity projects built around National Social Hygiene Day. The co-operation of the Boston Health Department has been assured.

On two hundred billboards throughout Massachusetts have appeared posters bearing the legend, "Safeguard Baby's Right to be Born Healthy—Every Expectant Mother Should Go Early to a Physician for an Examination and Blood Tests." The outdoor-advertising companies are contributing to this educational project to aid in the control of congenital syphilis.

The Committee on Postgraduate Medical Instruction of the Massachusetts Medical Society, with the co-operation of the Massachusetts Department of Public Health, the United States Public Health

Service, the Federal Children's Bureau and representatives of the Massachusetts Society for Social Hygiene are painstakingly preparing, under the direction of a member of the Department of Education at Harvard University, illustrated courses which contain all the essential facts concerning the diagnosis, treatment and public-health aspects of syphilis and gonorrhea. These will be given in various districts throughout the State during the winter and spring and are open to all registered physicians. It is hoped that the major clinics in Massachusetts will be equipped, in the not too distant future, with teachers for the postgraduate instruction in these important public-health problems.

NATIONAL POLIOMYELITIS FOUNDATION

AN announcement has come from President Roosevelt of the plan to form a national foundation for the purpose of unifying the fight against infantile paralysis, according to a report in *Science*. The new foundation will be financed through a nationwide solicitation of private charities, with an expected goal of from \$7,000,000 to \$10,000,000 in the next five years.

The President has a particular interest in the battle against this crippling disease and has been president of the Georgia Warm Springs Foundation since it was first organized over ten years ago. In his own words, the time has now arrived when the whole attack on this plague should be led and directed, though not controlled, by one national body. This foundation will make every effort to ensure that every responsible research agency in this country is adequately financed to carry on investigations into the cause of infantile paralysis and the methods by which it may be prevented.

We may hope that the launching of this new great health foundation will indeed furnish a landmark in the constant struggle of science to control disease. Some of the most devastating of the scourges of mankind have been conquered by the toil of silent workers, sometimes with little assistance, sometimes with the aid of great founda-

tions. This particular disease—probably the first to become the focal point of an entire organization such as this will be—makes up in dramatic interest and emotional appeal what it lacks in actual epidemiologic importance.

The suddenness with which infantile paralysis strikes, reaching out to waste the limbs of those who have hardly yet had time to use them, makes it a disease more dread than rheumatic fever, which cripples so many more, or than pneumonia, which exacts a much higher toll of lives.

The country and the world will wish all success to the National Foundation for Infantile Paralysis, hoping that through its efforts better treatment for this disease will result, and more devoutly to be wished for, some means of real control such as have been given us for smallpox and diphtheria.

PAPERS FROM THE FAULKNER HOSPITAL

IN this issue of the *Journal* is the first of a series of papers submitted by the staff members of the Faulkner Hospital. Through an arrangement with the Board of Trustees of the hospital the *Journal* will publish a group of these papers quarterly, and each group will be reprinted in pamphlet form with a special cover. Physicians desiring to obtain copies are requested to write to Dr. James A. Halsted, Faulkner Hospital, 1153 Centre Street, Jamaica Plain.

OBITUARY

CHARLES MORTON SMITH

1867-1937

The sudden death of Dr. Charles Morton Smith on January 8 following an illness of only twenty-four hours, came as a shock to his many friends both in and outside the profession. Although previously he had experienced warnings of impending disease, yet he refused to spare himself, carried on his customary routine of practice, and preferred not to let it be known that he suffered any ailment.

Dr. Smith was born in Dublin, New Hampshire, and after adequate preparation in the public schools, entered the Harvard Medical School, from which he was graduated, cum laude, in 1894. He

served as surgical intern at the Boston City Hospital, following which he started as a general practitioner in Boston. He very soon took up dermatology and became an assistant to the late Dr. Abner Post. He then gave up general practice and devoted himself exclusively to the practice of dermatology and syphilis.

He served at one time on the dermatological staffs of the Boston City Hospital and the Boston Dispensary. It was his early ambition to gain a thorough knowledge of syphilis and to become known as a specialist in that disease, and certainly that ambition was realized when in later years, together with Dr. Post, he organized the Department of Syphilis at the Massachusetts General Hospital and was appointed clinical professor of syphilology at the Harvard Medical School. His teaching and practice helped to stimulate the modern conception and advance in the diagnosis and management of venereal disease. He was among the first to appreciate the value of the Wassermann reaction in the diagnosis of syphilis and the use of arsphenamine in treatment.

He was a member of the national and state medical societies, and was affiliated with the American Dermatological Association and the New England Dermatological Society, as well as other smaller organizations. He was alert to everything that was progressive in medicine, especially in the field of dermatology.

Dr. Smith's personal devotion to the welfare of his patients was unusual. He spent much time in listening to the history of their ailments, and was equally painstaking in their subsequent care and treatment. He had a genial and kindly disposition so that he at once won their confidence and co-operation. He was most efficient in every way, and as a result, many of his patients became his grateful and lifelong friends.

One of his diversions was the care of a garden at his summer home in North Scituate, in which he did most of the work himself, even after he had been given warnings of failing health. Flowers and vegetables from this garden were generously distributed among his more intimate friends. He was a member of the Hatherly Country Club, and at one time attained considerable proficiency in golf.

He had an ear for good music, and a taste for everything that was artistic. Because of his keen sense of humor, he thoroughly appreciated a good story or a good joke. He was a most agreeable companion and a gracious host. Kindness, fairness, and good judgment were apparent in all his activities. Whatever he undertook to do was carried through in a thorough manner.

CASE HISTORY No. 56 PREMATURE SEPARATION OF PLACENTA AT SEVEN AND A HALF MONTHS

Mrs. D., aged thirty-nine, seven and a half months pregnant, was seen in consultation on February 13, 1928. About two hours before admission to the hospital the patient was seized with a sudden, sharp pain in the abdomen, followed by a gush of blood from the vagina. The severe pain was succeeded by a "dull ache and tense feeling" in the abdomen and lower back. Moderate flowing, with faintness and dizziness, continued, but there was no loss of consciousness. She was then transferred to the hospital.

The family history and the patient's past history were negative. There is no record of catamenial history as the patient was seen in consultation with a doctor who is now deceased. She had had four full-term deliveries, the first a forceps delivery and the others normal. The children were all living and well, and there had been no miscarriages. In 1926, a colpoperineorrhaphy, appendectomy and uterine suspension were performed.

This pregnancy was uneventful until January 1 when a moderate albuminuria and slight rise of blood pressure were noted. The usual treatment was instituted: rest and restriction of proteins and salt, with saline catharsis. Observation during this period disclosed no increase of albumin, and the blood pressure persisted between 140 systolic, 40 diastolic and 150 systolic, 100 diastolic.

The patient was a well-developed and nourished woman, who was conscious and rational but very anxious and apprehensive. There was marked pallor of the skin and mucous membranes. The heart showed no enlargement, there were no murmurs. The blood pressure was 146 systolic, 96 diastolic. The lungs were clear and resonant, there were no rales, and the respirations were 28 per minute. Her temperature was 97.8°F., and the pulse 126. The abdomen was distended by a pregnant uterus rising to four fingers below the ensiform. There was extreme tenderness over the entire uterus, with that tense, ligneous quality of the uterine wall which is observed in many cases of severe accidental hemorrhage. The fetal heart was heard in the right lower quadrant, faint and irregular, the

A series of selected case histories by members of the section will be published weekly.
Comments and questions by subscribers are solicited and will be discussed by members of the section.

rate ranged from 108 to 134 beats per minute. There was a moderate but continuous flow of blood.

Rectal examination showed that the cervix was one-finger dilated and was partly effaced with the vertex presenting and high. By pressure on the fundus, the head could be forced firmly against the cervix and no placental tissue could be felt. There was slight edema of the ankles.

Urinalysis showed a specific gravity of 1.018, there was no sugar, and a trace of albumin. The sediment containing few red cells and no casts. A blood examination showed a red-cell count of 3,690,000, a white-cell count of 8400 and a hemoglobin of 55 per cent.

Conservative care was considered and rejected. The symptoms were so severe that a sanguineous infiltration of the myometrium was suspected. This might prevent postpartum contraction and result in fatal hemorrhage after delivery.

A low cervical cesarian section and supravaginal hysterectomy were then performed under nitrous oxide and oxygen anesthesia with a small amount of ether. About a liter of serosanguineous fluid was found free in the peritoneal cavity. The uterus was dark purple with many ecchymotic areas mottling its surface. The operative area was walled off, the vesicouterine fold of the peritoneum incised transversely and the bladder stripped off the lower uterine segment. The latter was then incised longitudinally and a small, living baby extracted. The placenta was detached over two thirds of its surface. The uterine wall at the line of incision, in spite of its location, was twice as thick as usual and so spongy and friable that the sutures would not hold. Frothy blood oozed freely from the cut edges. This condition, with the fact that the boggy, hemorrhagic uterus would not contract, made hysterectomy imperative. The uterus was quickly removed in the usual manner. Almost the entire cervix was exposed before firm tissue, which could be sutured, was reached. The cervical stump was suspended and peritonealized and the abdomen closed in layers without drainage. Glucose and saline solutions were administered intravenously and per rectum.

The pathologist's report was as follows: The uterus was 12 cm long, 10 cm laterally, 5.5 cm anteroposteriorly, the organ was deep red. An incision 7 cm long was present in the midline of the lower portion of the anterior wall. The surface of the uterus showed diffuse subperitoneal hemorrhage. On opening, the canal was 9.5 cm long and dilated, the anterior surface of the right side was covered by a thick layer of recent clot. Microscopic examination showed the muscle fibers separated and the lymphatics distended and empty. The veins were dilated, some were filled with blood. About many of these distended vessels

the surrounding tissues were filled with blood, this was notably so in subperitoneal regions. Many of the smaller veins contained numerous polymorphonuclear leukocytes. The muscle fibers were hypertrophied, some were swollen, almost hyaline in appearance and showed no nuclei.

The patient made a good recovery. The blood pressure and urine were normal after the fifth day, and she was discharged fifteen days after operation. At birth the baby weighed 3 lb, 11 oz. and was gaining when discharged. When seen six weeks later the mother was in excellent health. The cervical stump was high, and the pelvis clear.

Comment. A diagnosis of premature separation of the placenta is made by some external bleeding, the tightness of the uterus, the absence of the fetal heart (if the placenta is entirely separated), and the condition of the patient from hemorrhage entirely out of proportion to the amount of blood lost externally. It is in the case of the partially separated placenta, when the baby is known to be alive, that differential diagnosis is often difficult. In such cases, a vaginal examination ruling out placenta previa of any type is the method of arriving at a correct diagnosis. If a placenta is felt, the patient has a placenta previa, if no placenta is felt, the patient has a separated placenta. The treatment of cases such as this one usually depends upon whether the patient is in labor. If, on examination, one finds the cervix taken up and partially dilated, rupturing the membranes and applying some sort of fundal pressure is the conservative operation. At seven and a half months one must realize that the safest procedure for the baby is cesarian section, but one must also appreciate that a seven and a half months' baby, even if born alive, has a definite chance of dying from prematurity. If the patient is not in labor, and the baby viable, cesarian section is the operation of choice, and if, as in this case, the operator feels that the uterus is one that may demand removal the abdominal route is the only way to treat the condition. In all severe bleeding cases, let it be remembered that transfusion is often necessary and that a donor should be on hand in every case.

COMMITTEE ON STATE AND NATIONAL LEGISLATION

As of January 10, the committee reports on the following bills

CLASS ONE

Bills introduced for the society

1 AN ACT regulating the sale of aminosulfamidobenzene and dinitrophenol

Be it enacted by the Senate and House of Representatives in General Court assembled, and by the authority of the same, as follows:

SECTION 1 Chapter two hundred and seventy of the

General Laws, as appearing in the Tercentenary Edition, is hereby amended by inserting after section two A the following new section

Section 2B Whoever sells aminosulfamido-benzene or any chemical combination, compound or derivative thereof, or dinitrophenol or any chemical combination, compound or derivative thereof, without the written prescription of a physician shall be punished by a fine of not more than fifty dollars. This section shall not apply to sales made by wholesale dealers or manufacturing chemists to retail dealers, or to sales of the above articles for non medicinal purposes.

Comment This bill has not yet received a number of conferences have been held with the legislative committees of the Retail Druggists Association, the Massachusetts Central Health Council, the Boston Health League, and the State Department of Public Health. They will all support this bill.

* * *

2. AN ACT requiring the clerk or registrar of each city or town to give to each person, who files notice of intention of marriage, suitable information concerning gonorrhea and syphilis.

Be it enacted by the Senate and House of Representatives in General Court assembled, and by the authority of the same, as follows

SECTION 1 Chapter two hundred and seven of the General Laws, as appearing in the Tercentenary Edition, is hereby amended by inserting after section twenty the following new section

Section 20A The clerk or registrar who administers the oath, as provided in the foregoing section, shall hand to each person to whom said oath is administered such literature, concerning gonorrhea and syphilis and the importance of premarital examination, as may be furnished for that purpose by the State Department of Public Health.

SECTION 2 Chapter two hundred and seven of the General Laws, as appearing in the Tercentenary Edition, is hereby further amended by inserting after section fifty two the following new section

Section 52A Whoever violates any provision of section twenty A shall be punished by a fine of not more than one hundred dollars

Comment This bill is introduced following a conference with leading specialists. It is likely that one or more bills requiring compulsory examination for syphilis will be introduced this year. It is believed by excellent authority that such acts would probably produce much less in the way of important good results than their proponents expect. If an obviously unworkable bill is introduced it might easily put the profession in a false position if it tried to oppose it or even if it ignored it. It is quite possible that a noncompulsory bill such as this would accomplish as much good as a compulsory bill. The State Department of Public Health will support us in this bill and will oppose any compulsory bill that it has seen as yet.

CLASS TWO

Bills introduced by others but recommended to the Council for support

1. House Bill No. 39 AN ACT relative to the meaning of the terms "rendering medical service," "practice of medicine" and "holding one's self out as a practitioner of medicine."

Be it enacted by the Senate and House of Representatives in General Court assembled, and by the authority of the same, as follows

Chapter one hundred and twelve of the General Laws, as appearing in the Tercentenary Edition thereof, is hereby amended by inserting after section five the two following new sections

Section 5A For the purposes of sections two to twelve A, inclusive, rendering medical service shall constitute the practice of medicine and shall include any treatment of one person by another, by the use or misuse of any means, for the purpose of diagnosing, preventing, relieving or curing any deviation from normal condition of mind or body, or for the purpose of preventing, diagnosing or interfering with pregnancy

Section 5B For the purposes of sections two to twelve A, inclusive, a person shall be regarded as holding himself out as a practitioner of medicine if he announces to any other person or to the public, a desire, willingness or readiness to practice medicine either directly by his own acts or indirectly through the acts of a servant or agent or if he opens an office for the practice of medicine, or if he appends to his name M.D., M.B., Dr., Doctor, Physician, Surgeon, Healer, Specialist, or any other title word or letter tending to suggest or designate him as a practitioner of medicine in any of its branches.

Comment The Board of Registration in Medicine feels that this definition will make the conviction of illegal practitioners more certain when they are brought into court.

* * *

2. House Bill No. 40 AN ACT to exempt dentists, optometrists and chiropodists (podiatrists) in certain cases from the penalties provided for the unlawful practice of medicine.

Be it enacted by the Senate and House of Representatives in General Court assembled, and by the authority of the same, as follows

Chapter one hundred and twelve of the General Laws, as appearing in the Tercentenary Edition thereof, is hereby amended by adding in line nineteen of section seven, the following sentence. They shall not apply to dentists, optometrists or chiropodists (podiatrists) when duly registered by their respective boards of registration and practicing as authorized by their certificates of registration, — so as to read as follows

Section 7 Sections two to six, inclusive, and section eight shall not be held to discriminate against any particular school or system of medicine, to prohibit medical or surgical service in a case of emergency, or to prohibit the domestic administration of family remedies. They shall not apply to a commissioned medical officer of the United States army, navy or marine hospital service in the performance of his official duty, to an interne or medical officer registered as provided in section nine, while engaged in the practice of medicine as authorized by said section, to an assistant in medicine registered as provided in section nine A, while engaged in the practice of medicine as authorized by said section, to a physician or surgeon resident in another state who is a legal practitioner therein, when in actual consultation with a legal practitioner of this commonwealth, to a physician authorized to practice medicine in another state, when he is called as the family physician to attend a person temporarily abiding in this commonwealth, nor to registered pharmacists in prescribing gratuitously, clairvoyants or persons practicing hypnosis, magnetic healing, mind cure, massage, Christian Science or cosmopathic method of healing, if they do not violate any provision of the preceding section. They shall not apply to dentists, optometrists or chiropodists (podiatrists) when duly registered by their

respective boards of registration and practicing as authorized by their certificates of registration.

Comment This amendment would prevent the possible prosecution of dentists, optometrists and chiropodists for practicing medicine so long as they stay in their own fields.

* * *

3 House Bill No 42 AN ACT relative to the revocation or suspension of certificates of registration to practice medicine and to the cancellation of such registration.

Be it enacted by the Senate and House of Representatives in General Court assembled, and by the authority of the same, as follows

Section two of chapter one hundred and twelve of the General Laws, as most recently amended by sections one and two of chapter two hundred and forty-seven of the acts of nineteen hundred and thirty six, is hereby further amended by striking out the fourth and fifth sentences, as appearing in the Tercentenary Edition, and inserting in place thereof the following

The board after hearing, may revoke any certificate issued by it and cancel the registration of any physician convicted of a felony, and may subsequently but not earlier than one year thereafter, reissue any certificate so revoked, and register anew any physician whose registration was so cancelled. The board after hearing, may suspend any certificate issued by it and cancel for a period not exceeding one year, the registration of any physician, who has been shown at such hearing to have been guilty of gross and confirmed use of alcohol in any of its forms while engaged in the practice of his profession, or of the use of narcotic drugs in any way other than for therapeutic purposes, or abuse of the authority granted in section two hundred and nine A of chapter ninety-four, or of publishing or causing to be published, or of distributing or causing to be distributed, any literature contrary to section twenty nine of chapter two hundred and seventy-two, or of acting as principal or assistant in the carrying on of the practice of medicine by an unregistered person or by any person convicted of the illegal practice of medicine or by any registered physician whose license has been revoked either permanently or temporarily, or of aiding and abetting in any attempt to secure registration, either for himself or for another, by fraud, or, in connection with his practice, of defrauding or attempting to defraud any person.

Comment This bill is of technical interest only. There is a conflict in two sentences in the present law, one of which allows the Board to suspend a license for a short period as a penalty for certain crimes, but the other of which does not allow the restoration of a suspended license until the next calendar year.

* * *

4 House Bill No 43 AN ACT relative to the qualifications for membership on the Board of Registration in Medicine.

Be it enacted by the Senate and House of Representatives in General Court assembled, and by the authority of the same, as follows

Section ten of chapter thirteen of the General Laws, as amended by chapter eight of the acts of nineteen hundred and thirty two, is hereby further amended by striking out, in lines nine to eleven, inclusive, the words "and no more than three members thereof shall at one time be members of any one chartered state medical society;"—so as to read as follows

Section 10 There shall be a board of registration in

medicine, in the two following sections called the board, consisting of seven persons, residents of the commonwealth, registered as qualified physicians under section two of chapter one hundred and twelve, or corresponding provisions of earlier laws, who shall have been for ten years actively engaged in the practice of their profession. No member of said board shall belong to the faculty of any medical college or university. One member thereof shall annually in June be appointed by the governor, with the advice and consent of the council, for seven years from July first following

Comment This bill removes the restriction in regard to medical society membership that may have been important when there were active homeopathic and eclectic societies, but is only a nuisance at the present time.

CLASS THREE

Bill presented to the Council for action

House Bill No 41 AN ACT to require annual licensing of qualified physicians

Be it enacted by the Senate and House of Representatives in General Court assembled, and by the authority of the same, as follows

Chapter one hundred and twelve of the General Laws, as appearing in the Tercentenary Edition thereof, is hereby amended by inserting after section four the two following new sections

Section 4A Every person registered as a qualified physician, who is engaged in the practice of medicine within the commonwealth, shall annually in December transmit to the board a license fee of one dollar together with a statement made on a blank furnished by the board at his request and signed by him under the penalties of perjury, giving his name, his registration number, the date of his registration, his professional address and such other information concerning his medical education as the board may require, provided that such statement may be so transmitted at any time prior to April first upon the payment of a license fee of one dollar together with a further fee of one dollar for each month or part thereof that he is in default, and provided further that every registered qualified physician who withdraws from the practice of medicine within the commonwealth shall be exempt from transmitting such license fee or statement during the time of such withdrawal if he notifies the board in writing of such intended withdrawal. After such a withdrawal and prior to re-entering the practice of medicine within the commonwealth, every qualified registered physician shall transmit to the board a license fee of one dollar and the statement aforesaid. The board shall give to each qualified registered physician transmitting the fee and statement hereunder a certificate stating that he has complied with the provisions of this section and he shall display such certificate continuously in a conspicuous place in his office during the period covered by such certificate. Every person registered by the board as a qualified physician, who is engaged in the practice of medicine within the commonwealth, shall notify the board promptly of any change of his professional address, giving his new address in writing. Whoever, being duly registered under section two or corresponding sections of earlier laws, practices medicine or holds himself out as a practitioner of medicine within the commonwealth without complying with the requirements of this section, shall be punished by a fine of not less than five nor more than one hundred dollars.

Section 4B On the first day of March of each year the board shall publish a list of the qualified registered physi-

cians who have transmitted the fee and statement required by section four A during the preceding December, giving the name of each such physician, his registration number, the date of his registration, his professional address, and such other information as is specified in section four A, and shall send a copy of such list to each such physician, and to each town clerk, chief of police, board of health, hospital and registered pharmacy in the commonwealth.

Comment This bill was introduced by the Board of Registration in Medicine. There is considerable sentiment among some members of the committee that a proper bill for annual registration of physicians may be useful to the Board and not harmful to the profession. Also there is belief that annual registration may be passed some time whether we oppose it or not. We also believe that this bill is better than last year's bill. But, we oppose the provision for transmitting yearly to the board such other information concerning his medical education as the board may require. We also believe that the Board has not yet proved that annual registration is necessary by making such a survey of the problem of the unlicensed practitioner that the magnitude and seriousness of the problem can be estimated.

In the opinion of the committee there is no guaranty that the money collected under the terms of this bill would be available to the Board for carrying out the provisions of the bill.

CLASS FOUR

Bills recommended to the Council for opposition

Senate Bill No. 40 (actual wording omitted)

Comment. This is a bill to regulate the giving of transfusions. It has as its purpose the prevention of the transmission of syphilis to recipients of blood transfusions. It would entail reports on blood serologic tests of recipient and donor in the case of each transfusion, to be sent to the State Department of Public Health. The committee does not believe that this is a serious enough problem to make such legislation desirable.

* * * * *

In regard to national legislation we know of no immediate matters except that on July 28, 1937, the following resolution was introduced into the United States Senate by the Honorable J. H. Lewis, of Illinois. This has not yet come out from the Finance Committee.

AN ACT to provide medical aid for the needy and the stricken with illness who are unable because of poverty to provide treatment and hospitalization, also to establish all licensed medical practitioners as civil officers of the National Government.

Whereas the Federal Government has recognized its social responsibilities to its citizens by the enactment of the Social Security Act, and

Whereas an extension of such responsibilities is necessary to provide adequate medical care and attention for the impoverished and needy to assure the full enjoyment of social security, therefore be it

RESOLVED BY THE SENATE AND HOUSE OF REPRESENTATIVES OF THE UNITED STATES OF AMERICA IN CONGRESS ASSEMBLED, That all physicians and surgeons who practice the profession of medicine or surgery in the United States or its Territories are hereby declared to be civil officers of the United States for the purposes of this joint resolution.

Sec. 2. Any such physician or surgeon shall render such medical or surgical aid requested of him by any impoverished individual who is in need of such aid, and, where necessary, to order the hospitalization of any such individ-

ual. Any hospital to which such an order is directed shall, insofar as its facilities permit, provide for the hospitalization and care of any such individual in the manner best adapted to accomplish his recovery.

Sec. 3. Any physician, surgeon, or hospital rendering aid to impoverished individuals as provided in section 2 is authorized to make such charges for such aid as are reasonable and just. Bills for such charges shall be submitted to the Social Security Board, which is authorized and directed to pay them, under such rules and regulations as it may prescribe.

Sec. 4. (a) It shall be unlawful for any physician, surgeon, or hospital official or employee to refuse to render aid as provided for in this joint resolution, or to make exorbitant or excessive charges for such aid, or to make any charge against an individual to whom aid has been rendered in addition to the charge paid by the Social Security Board.

(b) It shall be unlawful for any person fraudulently to represent that he is impoverished for the purpose of receiving aid under this joint resolution.

(c) Any person violating any of the provisions of this joint resolution shall be deemed guilty of a misdemeanor and, upon conviction thereof, shall be fined not more than \$1,000, or imprisoned not more than three months, or both.

Sec. 5. The Social Security Board shall have power to make such rules and regulations as may be necessary to carry out the provisions of this joint resolution.

Sec. 6. There is hereby authorized to be appropriated such sums as may be necessary to carry out the provisions of this joint resolution.

Comment The committee wishes to oppose this resolution by having the Council pass the following resolution which is similar to one recently passed by the Illinois State Medical Society

WHEREAS, Senate Joint Resolution 188, introduced on July 28, 1937, in the Senate of the United States by Senator J. Hamilton Lewis, of Illinois, proposes to federalize the medical profession of the nation, making every licensed physician and surgeon a civil officer and subject to prosecution and penalization in the federal courts for special causes enumerated in the resolution, and

WHEREAS, Such action being clearly a case of class legislation is contrary to the principles of constitutional government and

WHEREAS, The obligation imposed by the Joint Resolution upon each licensed physician of rendering needed medical service to any and all impoverished who make application to him would inevitably overwhelm practitioners of outstanding reputation, create the necessity of elaborate machinery to determine who would qualify as impoverished or in lieu thereof open the way for fraudulent practices, political interference and tend to lower the standards of medical practice, and

WHEREAS, The authority reposed by the Joint Resolution in the Social Security Board would lead almost certainly to fee fixing by governmental agencies and would necessitate a nation wide accounting and investigating system that would add a tremendous indirect cost to the nation's bill for medical care and

WHEREAS, The penalties imposed by the Joint Resolution on persons who violate the provisions thereof are so exorbitantly severe as to create a detrimental and inimical psychology in the medical profession and

WHEREAS, The proposed plan would lend itself easily to political abuse and become a stepping stone to communistic and socialistic government, and

WHEREAS, Poverty itself is the fundamental cause of most

of the ills which the Joint Resolution seeks to cure and prevent through the superficiality of a superimposed medical service, and

WHEREAS, The enforcement of local laws already on the statute books would provide as adequately for the sick-poor as modern facilities and circumstances make practicable, and

WHEREAS, The needy now enjoy as adequate medical care as economic limitations and the vagaries of human nature would make possible under the proposed plan, therefore it be

RESOLVED BY THE COUNCIL OF THE MASSACHUSETTS MEDICAL SOCIETY IN REGULAR SESSION ASSEMBLED, That Senate Joint Resolution 188 is inimical to the best public interests, is un-American and unworkable, would result in monumental expenses without yielding compensating benefits, would lead to political corruption and tyranny and ought to be defeated, and, be it further

RESOLVED, That copies of these resolutions be forwarded to the President of the United States, to each Senator and Representative in Congress from Massachusetts and to the secretaries of the medical societies of the several states

CARE OF THE HAIR

Hair is the common right of all of us, along with life, liberty and the pursuit of happiness. It is defined in various ways, perhaps as 'woman's crowning glory,' perhaps in the highbrow manner of the dictionary as "the characteristic outgrowth of the epidermis forming the coat of mammals." But in spite of various definitions, we all know what hair is and are interested in it, especially so in keeping what we have, as we grow older. I wish, therefore, to say something about the composition of hair, about some of the things which affect its growth, and how to keep it healthy.

A hair is a slender solid thread of many layers of cells, containing a horny substance like that in the finger- and toenails, and in the outer layer of the skin. This thread starts from a small elevation at the very bottom of a tiny tube called the hair follicle. In the wall of each follicle are the openings of two or three oil glands which supply the hair and scalp with the amount of oil they need.

Hair was given to us to protect us and to make us more attractive. Hair was undoubtedly developed as a necessity in protecting ancient man in his struggle for existence in the cold regions of prehistoric times. This was centuries before we began to cover ourselves with clothes. Nowadays, as a feature of personal beauty, especially if it is vanishing, hair has become one of man's and woman's most cherished possessions. But hair is still in use as a protection, for to many of the modern youth the ownership of a hat is a rare occasion.

As you look at people's hair, you cannot help being impressed with the differences in amount and by the differences in color. So also is there considerable variation in texture, in the amount of oil or dryness present, in the amount and type of scaling, in its luster, and so forth. The factors which control or influence these variations are not definitely known. The kind of hair our parents and grandparents had, or the lack of it, accounts for some of these variations. Certain illnesses also cause changes in the scalp and hair, and an examination of the scalp will often tell the physician a great deal about the general health of its owner. We are finding that some of the internal glands and the way that these glands act upon each

other may have much to do with the growth of hair. Improper care or neglect, or of too much sun, may produce changes in the hair and scalp. Differences in the scalps of different people and the many possible causes of trouble with hair make it almost impossible to lay down any general rules for the care of the hair. There are, however, certain general points that can be applied to everybody.

Scalps, of course, need cleansing just as much as the rest of the body does, but how often depends upon what kind of a scalp you have. Regular washing with soap is a necessity, the interval varying with the individual scalp and perhaps measured more by the amount of dirt accumulated and the amount of dryness or oiliness than by any other factors. The average mild soap is satisfactory to most skins, while for very oily scalps tincture of green soap or a tar or sulfur soap is somewhat better. Thorough rinsing and drying are not only desirable but necessary.

Excessive dryness after the shampoo may be overcome by the rubbing into the hair of a small amount of oil, or perhaps using a mixture of alcohol and a little castor oil, the alcohol evaporating and leaving the oil upon the hair. The amount of oil to be used will depend, of course, upon the degree of dryness of the individual scalp.

Combs and brushes should be cleaned at frequent intervals. Do not forget that combs and brushes are intimate personal property and are not for use by other members of the household. In the best combs the teeth are smooth and wide apart, and their tips should be blunt. Metal combs, if well made, have an added advantage—they can be boiled and so sterilized.

Brushing is almost a forgotten art in these days of modern high speed living. But it should not be forgotten because it aids in cleansing and provides a certain amount of stimulation to the scalp and to the oil glands. The brush should be a moderately stiff one and not used with sufficient pressure to irritate the skin. Rhythmic repeated stroking with a brush is really another kind of massage of the scalp.

Many scalps are stretched tightly over the skull, and there is very little slide to such a scalp when you try to move it. Usually in this kind of a scalp the blood supply is not so good as in the persons with a loose scalp in which there is a thicker body of tissue between the bone and the skin. Such individuals need more frequent mechanical stimulation by brushing or massage in order to bring a better supply of blood to the scalp.

I have said that different people have different amounts of oil. Usually there is an excess of oil in young people. As the individual becomes older this excessive oil gland activity becomes less, although there are numerous people in whom an excess of oil persists throughout life. With the latter, of course, more frequent shampoos are advisable, and possibly a somewhat stronger soap. Those persons with a persistent dryness of the scalp or skin can cope with their problem by reversing this procedure, that is, they need to shampoo less often, using a milder soap with possibly a little oil worked into the scalp from time to time.

There are many diseases of the skin which can occur upon the scalp and some which involve only the hairy areas. It can be said of the scalp, as of any other part of the body, that the best preventive of disease is to maintain good general health and provide the proper and painstaking cleanliness for the type of hair and scalp you happen to be blessed, or cursed, with.

* * *

A Green Lights to Health broadcast given by Dr. C. Guy Lane on Wednesday January 5 and sponsored by the Public Education Committee of the Massachusetts Medical Society and the Massachusetts Department of Public Health.

Q You have not said anything about falling out of the hair. What causes it, and what can be done about it?

A. Falling out of the hair is a matter of considerable concern to many of us. Under normal conditions there is always some replacement since new hairs grow in where the old ones fall out. There are many types of hair loss, with many causes, and very often we are unable to find the exact cause. The parents or grandparents are frequently blamed and there is no doubt of a hereditary factor, but whether that factor lies in the scalp itself or has something to do with the internal glands, we are not sure. Disease in other parts of the body, either general or local, either acute or chronic, may have a very definite effect in producing hair loss. Local diseases of the scalp often result in hair loss which may be permanent, and sometimes scars are left. Curiously enough, certain diseases, even when severe, have practically no effect in producing a decrease in the amount of hair. Dandruff—so-called—in its numerous types may be the cause of a later loss of hair. Over-exposure to the sun and the continual daily wetting of the hair are considered to be responsible for some cases of baldness. In spite of all that is known, in numerous individuals with falling hair we cannot discover why it falls, even after careful investigation.

The variety of baldness which appears in middle age and beyond, which is characterized by gradual thinning of the hair on the top of the head and above the temples, is thought to occur as a result of changes in blood vessels and the lower layers of the skin which come as we grow older. The outlook in such cases is not good, particularly if your father or mother had the same trouble. There is no medicine you can take internally that will help, but attention to general health and local stimulating measures and massage will be more effective than anything else. Man's desire to retain this last vestige of his former glory has resulted in the invention and patenting of all sorts of hair restorers and other devices to prey upon this desire, but they have little to commend them so far as actual results are concerned.

Q After an illness accompanied by fever is falling hair a serious symptom?

A. No. Usually the hair will regrow as the person regains his strength and vitality.

Q I have a young friend whose hair is rapidly turning white. Can she safely have her hair dyed?

A. The agents usually employed for dyeing hair may produce an irritation of the skin, usually about the hair border on the face or neck. Most individuals are not sensitive to these dyes and such persons will suffer no inconvenience from their use. It is always advisable to have the dye tried first on a small area of the skin where there is no hair before allowing its application. If any irritation of the skin develops from this test, or upon use of the dye on the hair, do not use it any more.

Q You have mentioned dandruff. Will you tell me what it really is?

A. Dandruff is a term usually applied to any type of scaling in the scalp. It is a major problem for many people. Some little scaling is present in everyone. An abnormal amount may consist of many dry fine scales, or perhaps may be present in the form of thick greasy and possibly adherent scales. It may be all over the head, or appear in a few small patches. Such scaling may be the result of some inflammatory condition of the oil glands of the scalp or may be caused by some other disease of the scalp or by a diseased condition in another part of the body. No special germ has been found in all cases as a cause, in spite of glowing advertisements to the contrary. Many germs are found in the scalp, but it is hard to tell if they cause trouble or appear after trouble has started.

Q Does the sun actually inflict damage upon hair?

A. Yes. Over-exposure to the summer sun may dry out the hair and in certain instances, especially in the blonde types, may cause the hair to fall out. A moderate amount of sun or of artificial ultraviolet light, however, is very beneficial, in my opinion.

Q Does the addition of egg to the shampoo help any?

A. There may be a temporary gloss, and perhaps it renders the hair less dry for a while, but a small amount of oil is somewhat better.

Q Can you tell me whether the effect of a permanent wave is apt to be harmful to the hair?

A. The Bureau of Standards has found that excessive heat lowers the breaking strength of hair. The temperature applied in carefully administered permanent waves is below this critical point, and the hair should suffer no harm. Occasionally a burn is produced by a careless operator. Certain solutions are also used but in general they are not injurious. Individuals with very fine and quite dry hair should not have permanent waves so often as other persons.

MEDICAL POSTGRADUATE EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau, have been arranged for the week beginning January 31.

BRISTOL NORTH

Thursday, February 3, at 4 00 p. m., at the Morton Hospital, Taunton. Subject: Complications in Obstetrics, Illustrated by Case Histories. Instructor: James C. Janney. Arthur R. Crandell, *Chairman*.

BRISTOL SOUTH (New Bedford Section)

Friday, February 4, at 4 00 p. m., at St. Luke's Hospital, New Bedford. Subject: Early Syphilis. Instructor to be announced. Robert H. Goodwin and Howard P. Sawyer, *Chairmen*.

ESSEX SOUTH

Tuesday, February 1, at 4 00 p. m., in the Nurses Home, Salem Hospital, Salem. Subject: Rheumatic Infection, Rheumatic Heart Disease. Instructor: Edward F. Bland. Walter G. Phippen, *Chairman*.

MIDDLESEX EAST

Tuesday, February 1, at 4 00 p. m., at the Melrose Hospital, Melrose. Subject: Bleeding in the Last Trimester of Pregnancy. Instructor: Robert L. DeNormandie. Joseph H. Fay, *Chairman*.

MIDDLESEX NORTH

Friday, February 4, at 7 00 p. m., at St. John's Hospital, Lowell. Subject: Recent Advances in the Diagnosis and Treatment of Heart Disease. Instructor: Burton E. Hamilton. William S. Lawler, *Chairman*.

NORFOLK SOUTH

Monday, January 31, at 8.30 p. m., at the Quincy City Hospital, Quincy. Subject: Recent Advances in the Diagnosis and Treatment of Heart Disease. Instructor: Samuel A. Levine. David L. Belding, *Chairman*.

PLYMOUTH

Tuesday, February 1, at 4 00 p m, in the Rosa Field Nurses' Residence, Brockton Hospital (rear of hospital), Brockton. Subject Gonorrhea in the Male. Instructor George C Prather Walter H. Pulsifer, *Chairman*

WORCESTER (Milford Section)

Thursday, February 3, at 8 30 p m, in the Nurses' Home of the Milford Hospital, Milford. Subject Cesarean Section, Analgesia Instructor Joseph W O Connor Joseph Ashkins, *Chairman*

WORCESTER NORTH

Friday, February 4, at 4 30 p m, at the Burbank Hospital, Fitchburg Subject Recent Advances in the Diagnosis and Treatment of Heart Disease. Instructor William D Reid. Edward A Adams, *Chairman*

NEW HAMPSHIRE MEDICAL SOCIETY

GREETINGS AND BEST WISHES

May our Society grow, and increase in all that is Good,
May our Institutions give a larger measure of Service,
May our Efforts for the Improvement and Advancement
of Medicine and Public Health, for the Welfare of the
Sick in Soul, and Sick in Body, bear Fruit as never
before,

This is our New Year Message.

HISTORICAL NOTES

The New Hampshire Medical Society is the fourth oldest in the United States The three older are Delaware, New Jersey and Massachusetts

* * *

The following note appeared in the November, 1838, issue of the *American Journal for Medical Sciences*

At the annual meeting of the N H Medical Society, holden June last, it was voted that this Society recommend an Annual National Convention, to consist of Delegates from the various Medical Schools and Societies in the Union, that the first Convention be proposed to be holden AD 1840, and that the Secretary send a notice of this vote to the *Boston Medical & Surgical Journal* and the *American Journal of Medical Sciences* at Philadelphia

JAMES B ABBOTT,
Secy N H. Med Society

Boscawen, Oct., 1838

* * *

Most doctors in the old days were forced to dispense drugs, some of which they grew in their own herb gardens. The available remedies were fewer in number, but this was made up by the amount used Kelley lists the drugs most commonly used, among which are calomel, tartar emetic, jalap, rhubarb, gentian root, chamomile flowers, tartaric acid and Burgundy pitch He quotes Carr, a country doctor with an average practice, as saying that he used one hundred pounds of Peruvian bark (cinchona) in a year

* * *

The first symphysiotomy in New Hampshire, and very likely the first in the United States, was done in Barnstead

in 1833 Prof C D Meigs said the operation had never been done in America. Sigault in 1768 proposed the operation, and in 1777 performed it on Mme. Souchet. The patient and her baby lived, though she had a permanent vesicovaginal fistula, fecal incontinence and difficulty of locomotion Sigault, however, received a gold medal for his enterprise. Churchill (*Am J M Sc* 45 172, 1838) reported on the results of the operation before the Surgical Society of Ireland in 1838 He collected two hundred and forty cases from the literature, but no American case. However, Dr Thomas Shannon, of Pittsfield, and Dr Simon Woodward, of Barnstead, did this operation on the wife of Dr Woodward (*Tr N H. Med. Soc.*, 1893, p. 16) The division of the symphysis was so complete that the baby's scalp was injured. However, both mother and child recovered

* * *

"We hear that Dr Waterhouse has received the matter of the cow pox from England, and that inoculation has succeeded in one of his children Upwards of 30 000 persons of all ages, in England, have passed through this disease." *Columbian Phoenix*, July, 1800

* * *

Dr Nathaniel H. Scott of Wolfeboro, fifty years a member of the New Hampshire Medical Society, was presented the gold medal at the June, 1937, anniversary In Dr Scott's practice occurred the first three cases of psittacosis, recognized as such in the United States. Dr Herman Vinkery saw the patients in consultation, made the correct diagnosis, and described the cases for the *Boston Medical and Surgical Journal*

BOARD OF REGISTRATION IN MEDICINE

The death of Dr Charles Duncan left the office of secretary treasurer vacant. Dr Fred E. Clow was elected to the position, and Dr Charles W Adams generously consented to continue as a member of the board. Three formal meetings of the board, and several informal ones, have been held The number of men licensed has exceeded that of any previous year An amendment to the Medical Practice Act requiring a one year internship took effect on January 1

The following have recently been granted registration certificates after examination

Francis Appleton
Herbert B Henderson
Louis Phillippe Gagnon
Louis Theobald
Joseph Clough
David W Barrow
Edward F Yurkanis
Jos Carroll McCarty
Phillipe J Cote
Daniel Jos Sabia
Wm. Plummer Clough, Jr
Donald J Flanagan
Claire Priscilla Myron
Alfred Lawrence Pimental
Lloyd Leslie Wells
Robert E. Maxwell

No candidate was failed this year

The following have been licensed by reciprocity

Celia Alma McNecley	New York
Herman Burian	Jugoslavia
Fred Ashley Almqvist	Vermont

Carl Oscar Louis Collin	Massachusetts
Percy Chandler Grigg	Pennsylvania
Robert T Terry	Missouri
Abraham Teitelbaum	New York
Israel Dinerman	Illinois
James G Bogle	Massachusetts
John B McKenna	"
Justin F Grant	"
Duncan M. Chalmers	"
Edward Lawlor	"
Richard Backus	Vermont
Gerhard Golm	New York
Madison Brown	Vermont
Addison Roe	New York
Lester Whitaker	Massachusetts
Wilhelm Perlstein	Prussia (German Reich)
Samuel J King	Massachusetts
Thomas Walker	New York
Cornelia Walker	"
Lorne A MacLean	Canada (Quebec)
Wm. Endicott Greer	Massachusetts
Bernard Gagnon	Maine
Violet M Crabbe	Michigan
Ludwig Mendelson	Prussia (German Reich)
Antoine Dubreuil	New York
Irving J Moffett	Missouri
Harlan Eugene Karr	Vermont
William A. Brady	"
Walter D Berry	Massachusetts
Wm. Elmar MacDonald	"
Ludwig Hirsch Hoffman	Bavaria (German Reich)
Margaret Warren Barnes	Montana

The following have been registered by endorsement of credentials (National Board of Medical Examiners)

Leo Herbert Hadler
Harry B Luke
Paul Porter Gates
Ellsworth Morton Tracy
Sven M. Gundersen
Simon Stone
Byron Lewin
Daniel McCooey
Harry L. Day

STATE BOARD OF HEALTH

Dr Travis Burroughs, secretary of the State Board of Health, announces that serums for pneumonia due to Types I, II, V and VII are available to physicians who send sputums to the State Laboratory of Hygiene at the State House, Concord. Other laboratories will be approved for typing as rapidly as technicians can be trained. Dr Burroughs advises that the mails or express should not be used for sending sputums. Messengers can be given serum, when indicated, within a very short time after the sputum is received at the laboratory.

* * *

The new form of Certificates of Death and Birth have been sent by the State Board of Health to all physicians. Complete instructions for preparing the new certificates have been prepared, but the department will gladly aid individuals and hospitals in the explanation of the new records.

COMMITTEE ON CONTROL OF CANCER

The Committee recently sent to all physicians in New Hampshire a letter from which the following is an abstract

CANCER OF THE UTERUS

Too many women are being discovered at the diagnostic and treatment centers of this state with advanced cancer of the cervix or uterine fundus. There are two obvious remedies for this situation

- 1 Pelvic examination of all women above the age of 35 followed by remedial surgery where there are uterine growths, or lacerations, ulcerations or erosions of the cervix. This would probably reduce the incidence of cervical cancer by 50 per cent.
- 2 Educate all women—beginning with the younger generation—that flowing between periods or after the menopause always means there is a pathological cause. *Educate women to the idea that an increase in flowing at the menopause is not normal and that there is always a cause* (Unfortunately, some physicians do not recognize this truth.)

Educate women in the knowledge that the very smallest blood discharge (spotting) is a more serious indication than free flowing. You should tell all your women patients to come for examination upon the least sign of abnormal bleeding.

When symptoms are present that may indicate the presence of cancer of the uterus a definite diagnosis should be made at once by (1) a biopsy specimen taken from the proper place and in the proper manner, from any erosion or growth of the cervix or (2) if the cervix is normal, by a curettage and an examination of all the curetted material by a competent pathologist

The percentage of cures in cancer of the cervix when it is confined to the cervix alone is high, about 80 per cent, and these figures can be approached if the above rules are followed.

SOCIETY NEWS

At the regular meeting of the Dover Medical Society on January 5 Frank Sulloway, Esq., of Concord, gave an address on 'Medical Defense Methods in New Hampshire.'

* * *

The Carroll County Medical Society met at the home of the president, Dr Louise Paul, at Wakefield, on the evening of December 5. Dr Dawson Tyson, of Hanover, read a practical clinical paper on 'Treatment of Pulmonary Suppuration.' Dr James E. Bovaird was chosen president, and Dr Charles Smith secretary-treasurer for the coming year. Miss Caroline Paul, technician at the Mary Hitchcock Hospital, acted as hostess with her sister. Drs. W. J. Paul Dye and Francis J. C. Dube were elected delegates to the New Hampshire Medical Society.

* * *

At a meeting of the Belknap County Medical Society in January, Dr Howard M. Clute, of Boston, spoke on 'Gall Bladder Disease.' Dr Clute's talk was exceedingly interesting and instructive, and a lively discussion followed.

DEATH

Dr Mary S. Danforth, for many years a busy physician in Manchester and the first woman member of the New Hampshire Medical Society, which honored her a short time ago with the gold medal for fifty years membership, recently died at her home in Manchester. Dr Danforth

who was a pioneer in medicine, had had a most successful career

PERSONALS

Dr John Lyle, formerly physician at Camp Belknap, began an internship at the Mary Hitchcock Hospital on January 4

Dr Harold Loverud, of Manchester, has been made a consultant in roentgenology to the Margaret Pillsbury Hospital

Dr Harry B Luke, of Huntington, Long Island, has opened an office for the practice of general medicine at Wolfeboro

Dr Andrew Oberlander, formerly of Reading, Massachusetts, who has been elected university physician at New Hampshire University, began his service on January 1

Dr Leo H Hadler has opened an office at Goffstown

Dr R. A. Hernandez, of Laconia, is on a six weeks' vacation in Cuba

NOTES

The Plymouth Hospital Association is making plans for an entirely new modern hospital.

The Laconia Clinic in Laconia is being formed and plans to begin to function in the early part of February, when it is expected that the new building which is being erected will be completed. The personnel is as follows Dr Smart (surgery), Dr R. A. Hernandez (ear, eye, nose and throat), Drs Perley, La France and Brown (medicine), Dr Robinson (urology), and Dr Sullivan (dentistry)

This is our first attempt to have a New Hampshire news section in each of the New Hampshire issues of the *Journal*. If you approve of the idea, send us some news. Suggestions for improvement will be welcome.

CARLETON R. METCALF, *Secretary*,
5 South State Street, Concord.

VERMONT STATE MEDICAL SOCIETY

RECENT DEATH

ALLEN—TRUMAN ALLEN, M.D., of Brandon, Vermont, died at his home, December 29, after a long illness. He was in his fiftieth year.

A native of Royalton, he attended the Royalton schools and Montpelier Seminary, and received his degree from the University of Vermont College of Medicine in 1912. His internship was served at the Mary Fletcher Hospital, following which he became assistant physician at the Vermont State Hospital in Waterbury, Vermont. In 1918 he was made clinical instructor in psychiatry at the University of Vermont College of Medicine and became assistant professor of neurology ten years later.

For nineteen years Dr Allen was superintendent of the Brandon State School and at the time of his death was neurologist at the Mary Fletcher Hospital in Burlington and neuropsychiatrist at the Rutland City Hospital. Dr Allen was a fellow of the American Medical Association and a member of the Vermont State Medical Society and the American Association on Mental Deficiency.

His widow, a son, a daughter, a brother and a sister survive him.

MISCELLANY

MORTALITY SUMMARY FOR 1937

Deaths in 86 major cities during 1937 dipped slightly under the 1936 figures, according to preliminary reports recently made by Director William L. Austin, Bureau of the Census, Department of Commerce. The infant death rate in these cities was also slightly lower last year, compared with 1936.

Deaths in the 86 cities in 1937 totaled 446,524 compared with 448,888 reported for 1936. The provisional infant mortality rate for the 86 cities is 47 per 1000 live births, compared with 50 per 1000 live births in 1936.

Although the number of deaths reported in 1937 was practically the same as that reported in 1936, several differences in the general mortality experience may be pointed out. In the last week of 1936 there was a sharp increase in mortality, largely due, presumably, to an increase in deaths from pneumonia and influenza. This excess mortality continued during the first two months of 1937, the number of deaths each week remaining above the average for the preceding three years.

Another notable feature in the 1937 mortality seasonal curve was a sharp increase in deaths due to the heat wave of last July. The heat wave at that time caused a considerable peak in the mortality curve, but there was a much greater effect during the excessive heat wave of July, 1936.

The 28,485 infant deaths reported for 1937 represent a decrease of 341, or 1.2 per cent, from the 28,826 reported for 1936. On the basis of estimated number of births there were, in 1937, 47 infant deaths for each 1000 births. Although this figure is provisional, it indicates a real decrease in infant mortality when compared with the comparable provisional rate of 50 for 1936 — *U S Department of Commerce*.

THE FOUNDATION PRIZE

Dr James R. Bloss, secretary of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons, has received so many inquiries concerning the rules governing the award of the Foundation Prize by the association that they are herewith given in full:

(1) The award which shall be known as The Foundation Prize shall consist of \$500.

(2) Eligible contestants shall include only (a) in terns, residents and graduate students in obstetrics, gynecology or abdominal surgery and (b) physicians

(with an M.D. degree) who are actively practicing or teaching obstetrics, gynecology or abdominal surgery

(3) Manuscripts must be presented under a nom-de-plume, which shall in no way indicate the author's identity, to the Secretary of the Association together with a sealed envelope bearing the nom-de-plume and containing a card showing the name and address of the contestant.

(4) Manuscripts must be limited to 5000 words, and must be typewritten in double spacing on one side of the sheet. Ample margins should be provided. Illustrations should be limited to such as are required for a clear exposition of the thesis

(5) The successful thesis shall become the property of the Association, but this provision shall in no way interfere with publication of the communication in the journal of the author's choice. Unsuccessful contributions will be returned promptly to their authors

(6) All manuscripts entered in a given year must be in the hands of the Secretary (Jas R. Bloss, M.D., 418 Eleventh Street, Huntington, West Virginia) before June 1

(7) The award will be made at the annual meetings of the Association, at which time the successful contestant must appear in person to present his contribution as a part of the regular scientific program, in conformity with the rules of the Association. The successful contestant must meet all expenses incident to this presentation.

(8) The President of the Association shall annually appoint a Committee on Award, which, under its own regulation, shall determine the successful contestant and shall inform the Secretary of his name and address at least two weeks before the annual meeting

CORRESPONDENCE

TEACHING OF OBSTETRICS

To the Editor My 'Note on the Teaching of Obstetrics,' which appeared in the November 4 issue of the *Journal*, has received so much unfavorable comment that perhaps a word of explanation is appropriate. It is not worth while to give all the criticism in detail, but two chief points may be noted. 'If the answer is easy, tell us, for we should like to know it,' and 'It is not possible to give an answer that all obstetricians will agree on as the way they would treat such a case. One critic claimed that the right answer to the question is, Nothing

It seems to me that there is a widespread misunderstanding on the question and its purpose. Of course there are unformulated hypotheses in the background and some of them are you are a physician and you have accepted the responsibility of giving your patient at her confinement the best care you can, up until labor is completed, labor has progressed normally until twenty minutes after the birth of the child, the placenta has not been delivered and there are no signs of separation of the placenta, give in detail the treatment you would employ up until the delivery of the placenta is completed.

It is a not unfair assumption that the physician does not leave the patient to take care of herself at the end of the twenty minutes, with a feeling of complete discharge of his responsibility, which is what the "nothing" implies. It would be a good thing for some obstetricians to

learn that they are not doing nothing for their patients when they refrain from operating on them. Perhaps the question may be criticized as not being explicit enough about the background, but a number of the candidates seemed to understand and wrote very creditable answers. Of these I said nothing in the note.

The purpose of the question was, first, to set a problem. Thus I think it did for nearly all, if not all, of the candidates. Not so, however, for the teacher of obstetrics whose answer is "nothing." For him there was no problem, yet he wants to know the easy and correct answer. Secondly, the question sought a solution for the problem. The solution may be sought along two lines—procedure or method, and information. The question is worded 'Give in detail' which may fairly include 'What would you do? How would you do it? When would you do it? Why would you do it?' There is a 'correct' answer which did not satisfy the examiner, yet I would call a 'con-sultant' is practically the part of wisdom for some physicians. Perhaps this corresponds to the 'nothing' to which reference has already been made.

There exists in the minds of some critics a confusion between the written answer and the answer in practice. The written answer proceeds with comparative ease because step after step, from the least to the greatest, is taken when, in the judgment of the physician, it should be taken. The difficulty in practice may be of comparatively great magnitude in finding out exactly when something else should be done, and just what this should be, that is, in making up one's mind and reaching a just judgment as to the next step. It is conceivable that in practice the physician may wisely pass in a comparatively short time from palpation of the fundus, in order to see if there is a second child in the uterine cavity, to hysterectomy. There would be reasons for this which the written answer should at least suggest.

It may be impossible to secure unanimity in the practical answer. One physician may say, 'In my opinion, now is the time to interfere. I don't like her looks. Another may say, 'I think we ought to wait another hour.' To the lack of thoroughness in the replies reference has already been made, but there is another point which the examination brought out to which I did not refer in the note. Comparatively few of the candidates exhibited any logical method of procedure. Yet after all, is not the teaching of correct method at least as valuable as the imparting of correct information as to facts?

STEPHEN RUSHMORE, M.D.

FICTION OR PROPAGANDA?

To the Editor The able editorial writer in the *Journal of the American Medical Association* has already dealt with Doctor Cronin's novel *The Citadel*, but I, nevertheless, feel that what appears to me to be the most important part of the book has been overlooked.

I found little in the novel to commend it as such. The story is thin though readable, the difficulties and discouragements of dispensary practice have been better and more poignantly described by Maygban and others, the failings of some members of the medical profession have been exposed thoroughly, if not charitably, by one of our writers of modern journalism, and many times before, appealing characters have literally been bumped off by motor vehicles for the purpose of adding needed tragic interest to the tale.

There is, of course, a segment of the public that seems

never to tire of literary smirching. Furthermore, when a book, for one reason or another, reaches the commercial heights of the best seller class, it virtually becomes a "must" item in every novel reader's agenda. And now *The Citadel* is to appear on the motion picture screen.

As I read Doctor Cronin's book my interest flagged until I came upon the name, Spahlinger. I wondered at the author's choice of Spahlinger as his prototype of ill treated geniuses and when I encountered the same name farther on in the text, my wonder increased. Then, when I read of the miraculous manner in which a nonmedical man salvaged a wreck of the hero's own malpractice, I could see in the novel only a brief for the supposedly abused man of science.

The miracle worker in the story came from the north western portion of the United States. Without benefit of medical education he had devised a system for the treatment of respiratory infections that worked wonders where England's best physicians had failed. His reward was persecution—a persecution which, for a time, also threatened the career of the hero. But, in true cinema fashion, sentiment, or sentimentality, prevailed, the hero was cleared of the outrageous charges, abandoned his questionable practices and returned to the fold to which all good and upright doctors belong.

There then came to mind the great to-do over the Duke Fingard method of treatment of diseases of the respiratory tract. Again the scene is England and the central figure is a nonmedical man—a chemist from the American North west who, with a battery of germicides and whatnot, alleges to cure his patients by a course of inhalations. The medical profession, despite the allegiance to the scheme of some members of the aristocracy and some gentlemen with many letters after their names, have been equally disdainful of the American chemist and his mode of therapy.

Spahlinger, Doctor Cronin's chemist martyr—Duke Fingard! To me the parallels are too close to be taken as mere coincidence.

BENJAMIN WHITE, M.D.

New York City

RECENT DEATHS

PARIS—WILLIAM PARIS, M.D., of 139 Washington Avenue, Chelsea, died recently. He was in his thirty-eighth year.

Dr. Paris received his degree from Tufts College Medical School in 1926. He was a fellow of the Massachusetts Medical Society and the American Medical Association.

MANIX—EDWARD T. MANIX, M.D., of 59 Lewis Street, Lynn, died January 20 after a short illness. He was in his fifty third year.

A native of Exeter, New Hampshire, he attended Exeter Academy and received his degree from Harvard Medical School in 1898.

Dr. Manix was a fellow of the Massachusetts Medical Society and of the American Medical Association. He was a member of the Oxford Club, of Lynn, and the Tedesco Golf Club, of Marblehead.

Two sisters in Exeter, New Hampshire, survive him.

REPORTS OF MEETINGS

MIDDLESEX SOUTH DISTRICT MEDICAL SOCIETY

A meeting of the Middlesex South District Medical Society was held at the Cambridge Hospital on Wednes-

day morning, January 19. About 200 members were in attendance. Dr. Fred R. Jouett, president, presided.

Dr. Frederic A. Washburn, director of the hospital, was introduced and made a short speech of welcome. He stated that the Cambridge Hospital had developed a much improved pathological and bacteriological laboratory, that it was co-operating with the Massachusetts Department of Public Health in its campaign against venereal diseases, that the hospital was a station for premature babies, and that pneumonia typing was being done there. He further stated that he hoped that the institution would become a truly community hospital.

The program consisted of a clinicopathological discussion of cases, as follows:

- 1 A Case of Hemophilia with Necrotizing Prostatitis and Terminal Septicemia. Drs. Bryant Wetherell and Arthur H. Crosbie.
- 2 A Case of Spontaneous Fracture of Femur Due to Metastatic Carcinoma. Dr. James W. Sever.
- 3 A Case of Chronic Glomerulonephritis. Dr. James H. Townsend.
- 4 A Case of Post transfusion Anuria. Dr. Donald E. Currier.
- 5 Two Cases of Arteriosclerotic Heart Disease. Drs. David C. Dow, Jr. and James H. Townsend.
- 6 A Case of Uterine Fibroids and Pregnancy. Dr. Henry T. Hutchins.
- 7 A Case of Gallstones with Death from Liver Shock. Drs. Hollis L. Seavey and Horace P. Stevens.
- 8 A Case of Severe Anemia with Enlarged Liver and Spleen. Drs. Newton S. Bacon and Stephen M. Biddle.
- 9 A Case of Bacillus-X Endocarditis. Dr. Lendon Snedeker.

The pathological and postmortem findings in all cases were discussed by Dr. Harold E. MacMahon.

At the termination of the meeting, Dr. Jouett announced that the postgraduate course in instruction will begin in March and will be given at the Cambridge City Hospital, without charge. The full program is to be announced at a later date in the *New England Journal of Medicine*.

A buffet luncheon was served after the meeting.

ALEXANDER A. LEVI, M.D., Secretary

GREATER LAWRENCE MEDICAL ASSOCIATION

The annual meeting of the Greater Lawrence Medical Association was held on Thursday evening, January 20, in the staff library of the Lawrence General Hospital.

The guest speaker was Dr. Chester S. Keefer, associate physician, Thorndike Memorial Laboratory, Boston City Hospital, and associate professor of medicine, Harvard Medical School. His subject was "What Can Be Done for the Patient with Arthritis?" Dr. Keefer delivered a splendid lecture on the various forms of arthritis and described old and new forms of treatment.

A fee table was adopted for the doctors practicing in Greater Lawrence, which comprises Lawrence, Andover, Methuen and North Andover. The fees were not raised, but merely brought up-to-date for the convenience of medical men of this community. This is the first fee table to be adopted in thirty years.

A committee of three was appointed to study the matter of sponsoring a series of weekly medical broadcasts over a local station.

Officers for the ensuing year were elected as follows: president, Dr. Nicandro F. DeCesare, vice president, Dr.

Edward H. Ganley, secretary, Dr J LeRoy Wood, treasurer, Dr John T Batal, directors Drs. Henry F Dearborn, Victor A Reed, Harold R. Kurth, Carl H. Eidam and Nicholas J Scarito

NOTICES

REMOVAL

RICHARD H. OVERHOLT, M.D., announces the removal of his office to 1101 Beacon Street, Brookline.

JOSEPH D. WHELAN, M.D., announces the removal of his office to 482 Beacon Street, Boston.

LAWRENCE CANCER CLINIC

The regular Lawrence Cancer Clinic, to be held at the Lawrence General Hospital, 1 Garden Street, Lawrence, on Tuesday, February 1, at 10 00 a. m., will be a demonstration and teaching clinic for physicians, with Dr Channing C. Simmons present as consultant. Physicians of the north half of Essex County are invited to accompany any of their patients whom they desire to have this service or to send them with a note. A report will be returned to every physician who sends a patient. The service is gratis. Any physician is welcome to attend the clinic.

This clinic is endorsed by the Committee on Postgraduate Instruction of the Massachusetts Medical Society

ROY V. BAKETEL, M.D.,
CHARLES J. BURGESS, M.D.,
JOHN J. MCARDLE, M.D.,
HARRY H. NEVERS, M.D.,
THOMAS V. UNIAC, M.D.,
J. FORREST BURNHAM, M.D., *Chairman*

TUMOR CLINIC, BOSTON DISPENSARY

Each Tuesday and Friday morning from ten to twelve thirty there is a meeting of the Tumor Clinic of the Boston Dispensary, a unit of the New England Medical Center. All kinds of tumors are seen, discussed, and when indicated, treated with radium and high voltage x-ray.

Physicians are welcome to visit this clinic and to bring a patient to the clinic for diagnosis.

BOSTON CITY HOSPITAL

A symposium on hepatic and biliary diseases will be held on Saturday, February 5, at 10 30 a. m. in the Thorndike Amphitheater. The papers to be presented are as follows:

1. Normal and Morbid Physiology of the Liver. Dr Stephen J. Maddock.
2. Pathology of Jaundice and Its Relations to Hepatic and Biliary Disease. Dr G. Kenneth Mallory.
3. Medical Aspects of Diseases of the Liver. Dr Chester S. Keefer.
4. Surgery of the Gall Bladder and Bile Ducts. Dr Irving J. Walker.

ROBERT M. GREEN, M.D., *Chairman*
COMMITTEE ON HOSPITAL CLINICS.

RADIO BROADCASTS

The fifth group of weekly broadcasts sponsored by the American Medical Association and the National Broadcasting Company concern preventing future illness. These dramatized health messages are intended to furnish supplementary material for health teaching in junior and

senior high schools and are broadcast every Wednesday from 2 00 to 2 30 p. m. over the Red Network. The dates and subjects are as follows:

February 2—Rheumatism and Arthritis. Known factors in the causation of arthritis and its care.

February 9—Healthy Hearts and Arteries. Known ways of protecting the heart against infection and hygienic abuse, how to live with heart disease.

February 16—Don't Fear Cancer—Fight It. Known factors in the cause, prevention and treatment of cancer.

February 23—Overcoming Diabetes. Individual efforts plus medical aid will win against diabetes.

WACHUSETT MEDICAL IMPROVEMENT SOCIETY

There will be a meeting of the Wachusett Medical Improvement Society at the Hotel Bancroft, Worcester, Wednesday evening, February 2, at 7 30. A dinner will be served at 6 30.

Dr J. Dellinger Barney will speak on 'The Problem of Urinary Lithiasis.'

WALTER D. BIEBERBACH, M.D., *President*,
N. S. SCARCELLO, M.D., *Secretary*

HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held in the Peter Bent Brigham Hospital amphitheater (Shattuck Street entrance), Tuesday, February 8, at 8 15 p. m.

PROGRAM

Presentation of Cases.

The Aging of Some Homeostatic Mechanisms. Dr Walter B. Cannon.

Medical students and physicians are cordially invited to attend.

MARSHALL N. FULTON, M.D., *Secretary*

CARNEY HOSPITAL

The monthly meeting of the Outpatient Department of the Carney Hospital will be held on Tuesday, February 1. Dr Benjamin Roseman will speak on "Membrana Tympani."

WILLIAM J. MACDONALD, M.D., *Secretary*

GREATER BOSTON MEDICAL SOCIETY

There will be a meeting of the Greater Boston Medical Society in the Beth Israel Hospital Auditorium on Tuesday, February 1, at 8 30 p. m.

Dr Charles Geschickter will speak on "Diagnosis and Treatment of Neoplasms of the Breast." Discussion by Drs. Charles Mixter, Reuben Davidoff and Harry F. Friedman.

K. C. ROSEN, M.D., *President*
D. B. STEARNS, M.D., *Secretary*

FAULKNER HOSPITAL

The usual clinicopathological conference will be held at the Faulkner Hospital for its staff and any other interested members of the medical profession on Thursday, February 3.

There will be a discussion of cases by Dr Franklin G. Balch, Jr., and Dr David L. Halbersleben.

A USEFUL TYPE OF LIGHT, WATERPROOF CAST

Preliminary Report

AUGUSTUS THORNDIKE, JR., M.D.,* AND WALTER E. GARREY, M.D.†

BOSTON

THE story of the use of splinting materials from the earliest records of the Egyptians three thousand years ago down to the present era of the plaster-of-Paris bandage is a fascinating one. This paper, however, can give only the high lights. It is of particular interest to find that the Egyptians used a combination of beeswax and rosin.¹ The natives of India, it is recorded, secured excellent results with clay molds.² Hippocrates was apparently familiar with rosin and wax.³ The European surgeons of the eighteenth and early nineteenth centuries preferred splints made from cloth saturated with albumen.⁴

The first attempt to devise lighter and less bulky splints was made about 1834, when Seutin quoted by Gamgee⁵ began using starched bandages. Monro⁶ credits Cheselden, Larrey and Dieffenbach with achieving the first adaptable use of plaster of Paris by making molds of a correctly reduced fractured limb in a wooden box. Matthysen⁷ was the first to think of impregnating coarsely meshed cotton cloth with powdered plaster, about 1852. At first this form of splint competed strenuously with starched bandage, then with dextrin, gutta percha and sodium silicate; it gradually won over all competitors through the manufacture of better cotton material or cotton cloth. Certain alterations and additions of a chemical nature—for example, salt and acetic acid—have produced changes in the setting time of the plaster, but generally speaking little if any change has taken place in the character of plaster-of-Paris bandage during the last twenty years.

Industrial chemistry has in recent years been producing in ever-increasing volume new and most interesting synthetic resins or "plastics." The opportunity to test the value of such materials for forming a rigid bandage or cast first presented

itself to the authors in February, 1937. Dextrin and gelatin bandages have been used extensively to form semirigid bandages. Celluloid and pyroxylin products have been used both to make casts and to waterproof plaster. But these mediums have been generally abandoned because of their inflammable or explosive character. Certain instances are on record of fire's occurring in a celluloid-coated cast, ignited by static electricity. Shellac has been used to coat plaster, but takes days to dry. Cellulose-compound casts were made about five years ago by Dr. Peirce H. Leavitt,⁸ of Brockton, but the material at that time had the disadvantage of being too coarse and too inflammable. It is of interest that our attention was attracted to synthetic resins, and that we have returned to a material somewhat like that which the Egyptians used over three thousand years ago.

Our interest in developing a light, waterproof rigid cast was aroused through the following case. The patient, a young man, had suffered a comminuted Colles's fracture with a fractured cuneiform. He was a fancy diver on the Harvard diving team, and was extremely anxious to continue his training during immobilization. It was thus necessary to construct a waterproof cast which would immobilize his wrist and be strong enough to withstand the stress of diving.

We followed Leavitt's original suggestion, and found that the makers of cellulose products had developed a very hard, light, waterproof material for making box toes for shoes. The important discovery had recently been made that adding boric acid to the cellulose compound rendered it but little more inflammable, *when dry*, than wood. The hard box toes were produced by molding a fabric impregnated with this compound while it was moistened with a solvent. Using this somewhat crude material, a very satisfactory cast was constructed for our patient, and was worn daily in the water for five weeks.

It then became of interest to see whether this

BOOK REVIEW

The Biology of Human Conflict. An anatomy of behavior—individual and social Triggant Burrow 435 pp. New York The Macmillan Company, 1937 \$3.50

This is an irritating book. Behind a barrage of neologisms, and a verbose and involved style, one feels there lies considerable gold. But the recovery of this gold involves much labor. A glossary of twelve pages tries to explain the meaning of some of the author's terms. At times, one is strongly sympathetic with others who have induced the author to write "When in reply, therefore, to the critic who complains that he cannot understand my work I say that I cannot either, I am not in the least at tempting to be facetious. The statement is perfectly true." The following sentence is a sample of the complex style and terminology "With the innovation of the organisms symbolic system of reactions and its concomitantly wider range of adaptation, apparently there came about the adoption of sectors of contact and communication with the outer world in which the radii of attention and interest are tangential to the organism's total bionomic axis of rapport."

The book contains an introduction and fourteen chapters divided into three parts "Organismic Psychology," "Organismic Morphology," "Organismic Pathology or Phylopathology."

The reviewer hesitates to take issue with what he has difficulty in understanding, namely, the author's thesis and the elaboration thereof. He doubts, however, whether the wars of the world, the problems of criminology and the problems of psychiatry can be properly studied on a basis of functional conflict without constantly considering the elements of mental defect and deterioration.

Figure 5 Model of cylindrical cast in which wire has been inserted for 'banjo' traction

lighter than plaster, extremely hard, waterproof, and pervious to x-ray. A much smaller quantity is required to provide rigidity than is the case with plaster of Paris. The cast does not, however, harden so quickly, taking on the average thirty to forty minutes to harden sufficiently for the pa-

tient to be dismissed, and a longer time before it cannot be indented.

We have used this material to make numerous casts, it was convenient to handle and was well liked by the patients. Its lightness and waterproof character are its salient advantages. On account of its lightness it has been used to make numerous casts for the upper extremities, both molded and circular, for fractures of the carpal bones, Colles's fracture and fractures of both bones of the forearm, and to make three shoulder spicas for

Figure 7 Fracture of the surgical neck of the humerus in a child six years of age after reduction, put up in a shoulder spica of cellulose-compound bandage.

fractured humeri. It has been particularly comfortable when applied to the figure-of-eight retainer in cases with fractured clavicles. Where waterproofness is desired, it has been found most satisfactory for double leg spicas in children. We have employed it on a number of toe-to-groin cylinders and leg boots and in conjunction with Bohler walking irons. One of us (A. T.) has had 4 patients swimming daily while wearing these casts. In arthritic patients they have been found most applicable. The light weight enables the patient to turn comfortably in bed, and the cast can be worn in the whirlpool and Hubbard baths. Our associate, Dr. R. J. Joplin, has used this material to

Figure 1 Bilateral fractures of the carpal scaphoids in a young man, twenty-one years of age Cellulose-compound 'cock up' casts

material could be supplied in a form in which it could be rolled on as readily as a wet plaster-of-Paris bandage, and be used for other types of casts. Numerous trials were carried out by impregnating various fabrics with the compound, that is, flannel strips, woven bandage, crinoline,

Figure 2. X-ray of case shown in Figure 1 taken through the casts

Figure 3 Fracture of both bones of the forearm just above the wrist in a child, seven years of age showing splints molded from cellulose-compound bandage

felts with scaved edges and cotton cloth. The present most acceptable product is rolled, untied, unbleached cotton sheeting, cut on the bias in 2- and 3-inch widths and supplied in 10 yard lengths. These bandages, correctly moistened with the quick-drying solvent, are supplied in hermetically sealed cans.

The casts made from this material are far

Figure 4 Fracture of both bones of the forearm in a child six years of age, showing cylindrical cast of cellulose-compound bandage

the skin, or by using stockinet. Sheet wadding may be used, although drying is not quite so rapid, on account of the slower evaporation of the solvent from the inside layer. The main factor required in drying is ventilation, and unless the

Figure 11 X-ray taken through the cellulose-compound bandage shown in Figure 10

material used for padding permits the access of air to the inside layer, the setting time is unduly prolonged. Cotton wadding may be substituted for the bandage or stockinet after the cast has been split or the molded splints have been removed for the first time. The danger of applying the cast too tightly and not allowing for shrinkage should be emphasized, this danger has been

Figure 12. Small infant with congenital hip put up after reduction in a cellulose-compound hip spica

minimized by providing an impregnated cloth cut on the bias. Owing to the rapid evaporation of the solvent it is advisable to open but one bandage at a time. Lamination may be prevented by painting the cast with some of the cellulose acetate lacquer (supplied in separate cans) the day after its application.

To acquire the technic of applying this type of cast takes practice and experience. One could

scarcely expect the first application to be any more perfect than that of plaster-of-Paris bandage.

The method of removal differs slightly from that used with plaster-of-Paris bandage. Cutting, bivalving or complete removal may be accomplished with the ordinary commercial type of plaster-cutter (Stille or Zimmer), or with a sharp knife having the arc of the usual surgeon's knife. A pointed plaster knife is unsatisfactory. When the cast is cut with a keen tool, a strip of thin, pliable metal, a throat stick, or a similar object should be inserted between the cast and the skin so as to

Figure 13 Fracture of both bones of the leg, middle third in a child five years of age, put up in cast of cellulose-compound bandage

avoid cutting the patient. A one-quarter inch strip of felt, applied when the cast is put on and lying along the site at which it will later be cut, will give similar protection. Owing to inherent factors in the hardened cellulose type of cylindrical cast, notably its resiliency in the horizontal plane or the plane in which the bandage is wound on, it is seldom necessary to cut the cast on more than one side for removal.

In reporting on a new type of rigid bandage, it is only fair to emphasize its disadvantages as well as its merits. Many patients object to the sickening odor of acetone present when the bandage is still moist. This odor disappears as drying or hardening takes place, adequate ventilation will mini-

construct jackets for painful arthritic spines (lightness being the advantage), to splint osteomyelitis cases, and to wedge deformed knees. We have utilized it for numerous protective devices for athletic injuries where lightness, great strength and waterproofing were in demand. Stitching may be done through the bandage with leather-working tools. Knee braces, shoulder and chest protectors and Thomas collars have been made. One forearm cast protecting a fractured carpal scaphoid was worn through two football games in heavy rain.

Figure 8 Shoulder spica for a refracture through the middle third of the left humeral shaft after operative reduction in a man sixty-two years of age

The method of application of the bandage, which is applied in either cylindrical-cast or molded-splint form, is similar to that adopted with plaster-of-Paris bandage, except that only three thicknesses are required, in certain areas of long or bulky casts, however, additional reinforcing slabs or circular layers may be required to counteract stresses or strains. This product has one outstanding advantage: should the cast crack at any point it is not destroyed, but can be mended with additional lacquer (solvent) and bandage. The mended bandage is as strong as the original, or even stronger. The incorporation of wire or steel (banjo wire or Bohler iron) results in a stronger bond between the parts than that when plaster of Paris is used. As stated, the bandage is packaged with the proper

amount of solvent so that it cannot dry. There is no dripping when the cast is applied, the whole process being a singularly clean one. The surgeon's hands may be protected from the collodion-like film by rubber gloves, the film readily flakes off later in any case.

In applying the casts, drying will be facilitated by laying three thicknesses of gauze bandage over

Figure 9 X-ray of case shown in Figure 8, taken through the spica and clearly showing bone repair and callus

Figure 10 Fracture of the left clavicle in a young man, twenty-one years of age, put up in a figure-of-eight retainer made of cellulose-compound bandage

extremely hard, and pervious to x-ray. Four possible objections to it have been cited, in every instance they are found to be of relatively slight importance, none precluding the use of this type of cast in conditions requiring a fixative bandage.

We are indebted to the industrial chemists Stanley Lovell and Gardener Pratt and to the research laboratory of the Arden Rayshine Company for their co-operation.

THE SURGICAL TREATMENT OF ABDOMINAL FISTULAS

SAMUEL F. MARSHALL, M.D.,* AND FRANK H. LAHEY, M.D.†

BOSTON

ABDOMINAL fistulas are uncommon complications of abdominal conditions, but still occur frequently enough to merit a consideration of their cause, origin and method of treatment. They may originate in any part of the gastrointestinal tract, from the biliary system, from the pancreas or from the genitourinary tract. We present a study of fistulas arising from the small and large intestine, together with reports of illustrative cases, including a case of pancreatic fistula in which the patient was successfully operated on by one of us (F. H. L.). We have purposely omitted from this group of cases all biliary, urinary and duodenal fistulas, since we believe that a report of these cases should comprise a separate study.

During the past ten years at the Lahey Clinic we have examined, and advised operation on, 37 patients with fistulas arising from the intestinal tract (Table 1). Of these, 27 were submitted to operation. During this period were seen many other cases of fistula in which operation was thought inadvisable or unnecessary. During the past year (1936) we have examined and operated on 6 patients, with a complete eradication of the fistula in all cases.

This group included a wide variety of ages, the youngest patient was two years old and the oldest seventy-six. Twenty-three patients ranged from thirty to sixty. Twenty-two were men and 15 were women.

Fecal fistula commonly results from sloughing of the bowel wall from severe infection, it may also be caused by injury to the adjacent loops of the bowel during an operative procedure. Severe trauma to the abdomen may be the primary cause

of a fistula, and the case of pancreatic fistula reported in this paper is an example of this. The primary cause of the fistula in our 37 cases is shown in Table 2.

The commonest cause of abdominal fistula is infection which produces gangrene and perforation of the bowel. In our series, appendicitis, diverticulitis of the colon and regional ileitis accounted for 23 of the cases. When the cecum was

Table 2 Cases of Abdominal Fistula Arranged According to Etiology

the point of origin, the fistula usually resulted from a direct extension of an appendicular infection to the cecal wall and was caused by sloughing of the wall from a severe fulminating infection, which produced gangrene. This occurred in 10 of the cases in which the primary condition was

mize it and will also shorten the hardening time. Since this product began to be supplied in hermetically sealed cans, thus eliminating the necessity for exposure of acetone in an open basin, those applying the material have noticed much less odor.

Another objection is that the setting time is long. The chemical substances that are known to lessen this period are too explosive and too dangerous to be considered. We have especially in mind propylene oxide. Efforts are now being made to

Figure 14 Models of leg casts: left leg cellulose compound; right leg plaster of Paris.

solve this problem. Yet even a setting time of as long as forty minutes does not preclude the use of this material, either for freshly reduced fractures, or in the convalescent stage of bone repair or under other conditions requiring fixation.

Those familiar with the use of pyroxylin, "air-plane dope," and similar products maintain that they shrink cloth so rapidly and completely that they could not be employed in a fixative bandage of this type. Our answer is that we have minimized shrinkage — (1) by using a special pyroxylin containing only 12 per cent nitrogen (instead of the ordinary 16 per cent), (2) by adding boric acid, and (3) by selecting a fabric cut on the bias, which permits the cloth to take up the shrinkage while drying.

The fourth objection is inflammability. This cannot be denied, however, the addition of boric

acid and the employment of pyroxylin containing only 12 per cent nitrogen have greatly reduced the inflammability. When the casts are thoroughly dry, that is, on the day after their application, they are no more inflammable than is wood. Sealing the moistened bandage in cans makes storage as safe as that of ether, and much safer than that of bottled collodion. The bandage is inflammable when wet, but much less so than collodion or ether, and it may be handled more safely than either.

The constituents and physiochemical properties involved are of interest. The hardening principle is entirely different from that of crystallization in plaster-of-Paris. Colloidal chemistry is involved, and hardness is achieved by evaporation with its gradual formation of millions of films in and around the fabric. The rigid bandage contains pyroxylin, boric acid and acetone. The boric acid, which is soluble in acetone, forms through the films myriads of particles which effectively diminish combustion. Twelve-per-cent nitrogen pyroxylin is less inflammable than ordinary collodion, and the final product is less dangerous than the modern x-ray film. The development of a pyroxylin of low viscosity makes it possible to include a large volume of pyroxylin in a given amount of plasticizer or solvent, and thus allows a tremendous film-forming concentration, which permits extreme rigidity.

No skin irritation has been observed in casts made of this bandage, many of which are applied or worn next the skin. No irritation would be expected from the individual constituents. Collodion is used therapeutically on irritated skins (treatment of poison ivy, herpes zoster, and so forth), and so is boric-acid powder. Acetone is an important part of Scott's solution, used to prepare skin and mucous membranes for operation.

At present the method appears to be most suitable for the convalescent care of fractures. The slower hardening renders its use in acute fractures more difficult, although not impossible. The material's being pervious to x-ray is an advantage in the fluoroscopic room, and later in following the progress of bone healing by callus formation. Much less bandage is required to supply the desired rigidity than is the case with plaster-of-Paris, and this makes the cost comparable to that of a plaster cast.

SUMMARY

A preliminary report is given of a useful type of material for making rigid casts. It is rolled or molded in similar fashion to plaster-of-Paris bandage. When dry it is waterproof, very light, ex-

most instances. A complete history frequently gives more accurate information as to the origin of the tract than does the roentgenologic examination, nevertheless, the latter should always be made, so as to establish the presence of obstruction, which is so often present, and also to indicate the pathologic condition involved. A roentgenologic examination made after injecting lipiodol into the fistulous tract will aid in determining the origin of the tract. It is necessary that the surgeon visualize

as accurately as possible the condition underlying the fistula, so that he may plan the scope of the surgical procedure needed to eradicate it. As pointed out previously, regional ileitis may have

a perforated appendix. The roentgenogram revealed a typical picture of regional ileitis, for which resection of the terminal ileum and ascending colon was necessary in order to obtain a cure. Needless to say, such an operation is a highly technical procedure, and involves a much greater risk than a simple closure of an opening into the cecum. Roentgenologic examination will also reveal the condition resulting from a diverticulitis of the colon, the presence or absence of obstruction and the presence or absence of fistulas in other viscera, and will assist materially in the planning of a sound surgical method. Following a severe inflammatory process in a colon which is studded with diverticula, the bowel is often thickened and stenosed from scar tissue, and this cicatrization and stenosis are likely to be permanent. The diverticula are readily outlined by a barium contrast enema, and the point of obstruction can be clearly seen (Fig 2).

In our series the duration of the fistulas varied between two months and seventeen years, 24 patients had had an abdominal discharge for more than six months, and 1 had had a discharge for seventeen years (Table 3).

It is true that a fistula of the cecum or of the small bowel is not usually a serious complication in

Table 4 *Data on Twelve Cases of Abdominal Fistula with a Duration of Less than Six Months*

AGE AND SEX	DURATION mo	CAUSE	REASON FOR OPERATION	OPERATION	FINAL RESULT

Fistula occurred after operation at the clinic

been the primary cause of a persistent abdominal discharge, if such is the case a much more radical operation will be required, and this must be planned for preoperatively. The case of a woman of twenty-three, with a fecal fistula of two years' duration, illustrates this well (Fig 1). Two operations had been previously carried out elsewhere for closure in the belief that the fistula arose from

the majority of cases, and most such fistulas tend to close without a major operation, this is particularly true if there is no obstruction of the bowel. Because of this we have carefully eliminated from our study many of the fistulas that occurred after operation for perforated appendicitis, and those which occurred after cecostomy or enterostomy had been carried out, in which healing resulted within

appendicitis Diverticulitis of the sigmoid flexure of the colon with perforation and formation of abscess was the cause of most of the left-sided abdominal fistulas, in 9 patients the fistula was of this origin In each of these cases the history was clearly that of diverticulitis, with formation of a fistula after drainage of an abscess in the left lower part of the abdomen On the other hand, when the small intestine was involved the fistula more commonly followed a secondary oper-

a perforation of the ileum With one exception all these had been referred to us after what was thought to have been an operation for a perforating appendicitis Four other cases in which the fistulous communication entered the small bowel apparently resulted from trauma, 2 of these followed gastric operations, 1 was caused by an injury to the ileum in a hernial sac, and 1 followed a severe injury to the abdomen Fistulas of the

Figure 1 Filling defect in the terminal ileum with moderate stasis and distention proximal to defect may be noted, the cecum also shows involvement with this inflammatory process

ation for pelvic abscess or for intestinal obstruction, and frequently it was caused by trauma to the small bowel In 6 cases in which a pelvic operation had previously been performed, an injury to the small bowel or to the rectosigmoid resulted from difficult operative procedures, and in each case the operation was complicated by serious adhesions resulting from previous surgery Regional ileitis must always be seriously considered as a cause of a right-sided abdominal fistulous tract, and in most cases in which the fistula is found to arise in the terminal ileum it proves to be the result of a localizing ileitis of this type We have operated on 15 patients with regional ileitis, of whom 4 had fistulas which arose from

Figure 2 Diverticulosis and diverticulitis of colon. The arrow points to irregular constriction caused by diverticulitis After the colon was emptied multiple diverticula were demonstrated

colon infrequently follow contraction of a colonic stoma, as in a series of 135 Mikulicz resections of the colon for carcinoma only 3 persistent fistulas have occurred subsequent to closure of the temporary stoma This complication is most often associated with an improper secondary closure of the stoma, and is caused by an obstruction to the passage of the intestinal contents through narrowing of the lumen of the bowel at the level of closure We have had but 1 case of persisting pancreatic fistula, and this originated from traumatic rupture of the pancreas, caused by injury to the abdomen received while playing football The case was successfully managed by transplantation of the fistula into the jejunum

The discharge of fecal material through an opening in the abdominal wall establishes very clearly the diagnosis of a communication with the intestine The source of a discharge, nonfecal in character, also may be determined readily, since the fluid can be identified by simple laboratory procedures, as in our case of pancreatic fistula The history may be of great assistance in establishing the part of the intestine involved, if it is studied in detail the origin of the fistula can be determined in

discharge. If the communicating sinus does not penetrate deeply into the abdominal cavity it may be removed without a wide opening into the peritoneal cavity. By far the larger number of cases require free, wide incision of the abdominal wall, a thorough release of adhesions, and open dissection of the tract, so as to obtain good exposure and protect the unaffected viscera with abdominal pads. If the tract can be followed throughout its course by the induration and thickening of its walls, the opening in the skin may be closed after complete dissection of the tract, leaking and contamination of the surrounding tissues thus being avoided. Traction upon the dissected part often outlines its direction. In some cases it is necessary to pass a probe along the course of the fistula as a guide in dissection.

The variety of methods of dealing with abdominal fistulas can be illustrated best by presenting 6 successfully treated cases, and describing the operative method employed in each case.

CASE REPORTS

Case 1* A man, aged 54, entered the New England Deaconess Hospital on December 1, 1936, for treatment of a fecal fistula in the right lower quadrant, which had

Figure 4 Reproduced by courtesy of *Surgical Clinics of North America* (17:791 1937). Location of the fistulous opening and the incision used in the operation are illustrated. The relation of the cecum and the appendix to the fistulous tract is demonstrated.

been present for one year. A femoral hernia on the right side had been repaired elsewhere in 1922, in 1927 an abscess developed in the operative scar, which opened and drained for 7 weeks, complete healing taking place after the discharge of a fecalith. In 1934 drainage was insti-

tuted for a gangrenous appendix, at this time the scar of the femoral hernia again opened and purulent material drained, both wounds healed after 10 weeks. A fecal fistula developed in the scar of the femoral hernia about 1 year before the patient was admitted to the clinic.

Physical examination revealed a draining fistula in the center of an oblique scar just below Poupart's ligament (Fig 4). Roentgenologic examination after injection of lipiodol revealed a large sinus, apparently connected with the large bowel.

At operation, December 3, an oblique incision was made parallel to and below Poupart's ligament, encircling the

Figure 5 Reproduced by courtesy of *Surgical Clinics of North America* (17:793 1937). The operative dissection is illustrated. The tract has been cleanly dissected from the femoral vein and is shown entering the stump of the appendix. Adequate exposure of the appendix and cecum is obtained by incising the fibers of the aponeurosis of the external oblique muscle and retracting the internal oblique and transversalis muscles. The peritoneum is opened but the operation is extraperitoneal because adhesions adequately protect the main peritoneal cavity.

fistulous opening in the skin. A probe was inserted into the sinus as a guide, and the tract was dissected free from the femoral vein up to the femoral ring (Fig 5). An incision was then made above the inguinal ligament through the aponeurosis of the external oblique muscle, the internal oblique and the transversalis muscles were retracted, and the peritoneum was opened. The deep epigastric vessels were divided between ligatures so as to give better exposure. The cecum with the appendix was easily identified, and was found to be well walled off with adhesions from the general peritoneal cavity, so that the latter was not opened. The tract was completely dissected, and the appendix, which opened directly into the tract, was removed and the stump carefully inverted. The femoral opening was then closed by suturing Poupart's ligament to Cooper's ligament. The muscles and fascia of the abdominal wall were closed in layers and a drain was placed in the region of the femoral canal. The patient was discharged 23 days after operation with only a slight seropurulent drainage from the wound. On February 27, the wound was entirely healed.

*Cases 1, 2, and 3 have been reported elsewhere (Marshall S. F. The surgical management of fecal fistula. *S. Clin. North America* 17:787 '37).

a few weeks. In such cases, provided no accompanying pathologic change can be demonstrated, the wound closes spontaneously and operation is unnecessary. We have included only the cases in which the fistula was permanent and in which there was no tendency of the lesion to heal spontaneously. Twelve patients, however, are included who had had fistulas for six months or less, most of whom required operation for relief. Table 4 presents these cases briefly and explains the necessity for operation.

If the more conservative measures, such as strapping with adhesive tape, cauterizing the edges of the openings, and simple closure with buttons (Fig. 3), do not result in cure, more radical operation is indicated. The operation for relief in these cases may be a serious one, it frequently taxes the ingenuity of the most experienced surgeon and calls for the highest degree of surgical judgment and skill. The operative technic must be planned for each case, and frequently the method of attack can be determined only as the condition is revealed at operation. The surgeon must in most cases anticipate an extensive procedure, must expect that a painstaking dissection will be necessary to eliminate the fistulous tract, and must guard against gross contamination of the peritoneal cavity from the spilling of intestinal contents or infected draining fluids. One of the more serious problems is the sterilization of the skin, which is almost impossible, and the prevention of local infection or peritonitis, since sterilization of the surrounding tissues cannot be satisfactorily obtained. Fortunately, in individuals who have had long-standing abdominal infections a marked local immunity develops and these wounds tend to heal readily without the development of serious inflammatory processes.

Another problem of importance is the determination of the presence of an intestinal obstruction. In practically every one of our cases one or more attempts at operative closure had already been made elsewhere. Failure had resulted because the problem of obstruction was not recognized. If the inflammatory process and scarring has produced marked narrowing of the intestinal lumen, this must be relieved. In many cases resection is necessary, and in such instances, particularly in the small bowel, we prefer to re-establish the intestinal lumen by closing the resected ends and performing a lateral anastomosis. It is our opinion that a lateral anastomosis in the presence of obstruction is safer than and preferable to an end-to-end anastomosis, because of the disproportionate size of the hypertrophied proximal intestinal loop, which does

not lend itself readily to an end-to-end anastomosis with the collapsed distal segment. A simple short-circuiting operation in these cases is unsatisfactory unless the fistulous tract is removed. If it is not, the fistula will continue to discharge either because of reverse peristalsis or because only a portion of the fecal current has been diverted.

Figure 3 Closure of fistulous opening with button technique. The opening is enlarged by incising, and an ordinary bone button is threaded on silver wire, introduced through the opening into the bowel, and anchored in place by tying a second button over the external opening.

When obstruction is associated with a fistulous tract communicating with the large bowel we prefer to employ a Mikulicz type of resection in addition to the excision of the tract, because of the greater margin of safety associated with this type of operation. This is especially true in the sigmoid flexure, where a high degree of obstruction frequently accompanies diverticulitis with an associated fistula. It must be emphasized also that in order to obtain permanent closure the tract must be completely excised, the thick, irregular, indurated edges of the opening into the bowel being entirely removed, and only relatively normal bowel wall being sutured. If the opening into the bowel is small, closure may be obtained by simple suture, otherwise, provision for restoration of an adequate lumen must be made.

Two methods of attack are useful in the eradication of fistulous tracts, one extraperitoneal and the other transperitoneal. Very few fistulas can be removed satisfactorily by extraperitoneal closure, even though this is the safest method and should be used whenever possible. This is particularly true of a fistula of the small intestine, because there is usually either a kinking of the intestine, or a narrowing of the lumen, which by obstruction leads to the persistence of the fecal

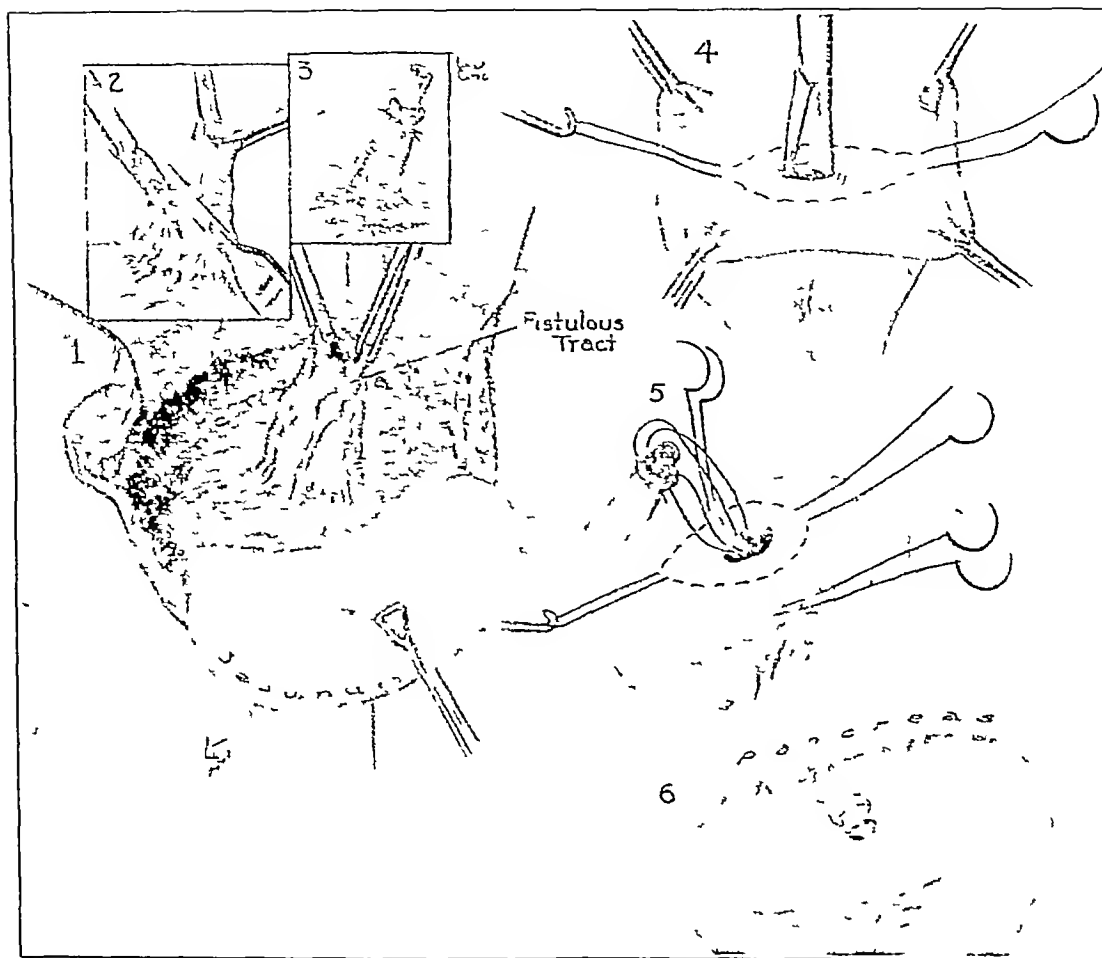

Figure 7 Reproduced by courtesy of *Surgery Gynecology and Obstetrics* (64 78 1937) Steps used in pancreaticojejunostomy (1) Fistulous tract to the pancreas cored out from the abdominal wall. Note the defect remaining on the right side of the incision where the tract was cored out. The jejunum has been brought up over the transverse colon preparatory to implanting the tract in it. (2) Paring the thick wall of the tract down to its base. In doing this special care must be exercised lest the wall of the tract be pared too thin perforated and the tract spoiled. (3) The prepared fistulous tract with a short section of catheter tied into it so that the purse string suture by which it is to be buried into the jejunum will not occlude it. Note the cuff of scar tissue left at the base of the tract to be attached to the jejunum to prevent the bowel's pulling away while the fistula is healing into the jejunum. (4) The method of preparing the opening into the jejunum for the implantation. The best opening with the least bleeding is made by forcing a closed sharp-pointed

goiter hemostat through the jejunum after the purse string suture has been inserted, and with the jejunum held in intestinal forceps. As here shown this opening with little or no bleeding can be dilated by the forceps to any size desired. (5) Two silk sutures which catch the end of the fistulous tract and are passed into the opening in the jejunum and out close to the mesentery. The traction sutures make it possible to guide the tract into the jejunum which even then is not an easy procedure. With the tract well inserted into the jejunum the purse string suture is tied snugly about the neck of the fistula until the tube in it obstruction will not result. The fine silk guide sutures emerging through the wall of the jejunum are now cut and withdrawn. (6) The cuff of scar tissue left at the base of the fistulous tract is now fixed to the wall of the jejunum by interrupted silk sutures front and back to prevent escape of the fistulous tract from the bowel and the operation is completed.

dominal exploratory operation had been done elsewhere 2 days after the accident, when a hemorrhage into the gastrosplenic omentum was revealed. A drain was inserted and the fluid from this drain proved to be pancreatic juice. Drainage continued for 7 weeks, when the patient left the hospital. The following day the fistula reopened. On December 30, 1935, roentgenologic examination elsewhere revealed a cavity to the right of the midline and about halfway between the anterior abdominal

wall and the spine, which was about 11 cm. in oblique diameter and 5 cm. in vertical diameter.

On examination at the clinic it was found that the abdominal incision was healed, in the upper third of the scar there was a fistulous opening which was discharging clear, opalescent fluid. A catheter was inserted into the sinus tract in order to collect and measure the fluid and to avoid leakage. Roentgenologic examination after lipiodol and sodium iodide had been injected revealed a

This case illustrates a fecal fistula arising from an appendix. The history points accurately to the appendix as the source of the fistula. In this case we were able to excise the tract and close the opening in the cecum without opening the general peritoneal cavity, which materially reduced the operative hazard.

Case 2 A man, aged 44, entered the New England Deaconess Hospital on February 27, 1937, because of a hernia in the right groin. At the age of 7 he had been ill subsequent to the development and drainage of an abscess in the right inguinal region. The sinus had drained for

Figure 6 Reproduced by courtesy of *Surgical Clinics of North America* (17:795, 1937). *Fistulous tract entering terminal ileum through femoral canal is demonstrated. The locations of the incisions are shown. This fistula followed a Richter's hernia of the small bowel.*

a long time but finally healed. He had had no further trouble except for a hernia in the right groin. One week before admission tenderness and induration had developed in the groin. An opening formed in the scar through which fecal contents drained.

Physical examination revealed a draining fecal fistula opening over the femoral canal just below Poupart's ligament. Palpation revealed the presence of a femoral hernia, gurgling of the intestinal contents beneath the skin was easily demonstrated. A diagnosis was made of a fecal fistula probably arising from a Richter's hernia of the small bowel.

At operation, the abdomen was opened through a right paramedian incision (Fig. 6), and the terminal ileum 15 cm. from the ileocecal valve was found to be adherent on its antimesenteric border to the sac of a femoral hernia. The fistulous tract entered the bowel, it was excised from the intestinal wall. The opening into the ileum was closed transversely and the lumen was not narrowed. The hernia was then repaired from within the abdominal cavity and the abdominal wall was closed without drainage. An oblique incision was made below and parallel to Poupart's ligament, the draining sinus was freed from the femoral vein by careful dissection, and the entire fistulous tract was removed. This incision was closed without drainage.

Recovery was uneventful and the patient was discharged 21 days after operation, when there was only a slight serous drainage from the inguinal incision.

This case illustrates a transperitoneal approach to a fistula of the small bowel which arose from a Richter's hernia of the terminal ileum into a femoral sac.

Case 3 A woman, aged 36, entered the New England Deaconess Hospital on February 13, 1937, because of a draining abdominal sinus of 4 years' duration. In 1919 an abdominal operation had been performed for a tuberculous abscess. The patient was confined to bed for 8 months and made a slow recovery. In 1933 an operation was done for a fibroid tumor and a second pelvic abscess was drained. After this operation the patient was confined to bed for 13 months. An abdominal fistula had persisted since that time. Undigested food was discharged from the fistula 2 or 3 hours after ingestion. The patient had had attacks of severe lower abdominal pain every 1 to 3 weeks, and these were followed by increased drainage from the fistula. Constipation had always been a marked feature.

Examination of the thorax did not reveal any evidence of tuberculosis, nor did the roentgenogram. There was a fecal fistula in the midportion of the suprapubic scar, and a fixed mass, adherent to a normal sized uterus, in the right side of the pelvis.

At operation, the midline suprapubic scar with its fistulous tract was excised and the peritoneum was opened. The pelvis was filled with adhesions, and the sigmoid flexure and rectum were densely adherent to the uterus. A firm, fixed mass filled the right side of the pelvis, and a probe passed through the fistula entered this mass. The left tube and ovary had been previously removed. After a painstaking dissection a supravaginal hysterectomy was done, and the right tube and ovary, which comprised the mass on the right side, were removed. The fistula entered the ileum, which was scarred and partially obstructed. The fistula was excised and the intestinal opening was closed, but this produced so much narrowing of the lumen of the bowel that it was necessary to perform an anastomosis between the terminal ileum and the transverse colon. A drain was inserted into the pelvis through the abdominal wound because of the marked degree of secondary infection present, although this procedure was considered undesirable because of the diagnosis of tuberculosis. The drain was removed within a few days. The patient made an uneventful convalescence and was dismissed 26 days after operation, at which time there was a slight serous drainage from the lower end of the incision. This drainage persisted for 6 months. Dr. Shields Warren reported that the specimen showed tuberculous endometritis, tuberculous oophoritis and tuberculous salpingitis.

This case is an excellent example of a fistula following a secondary operation for drainage of a pelvic abscess, and probably resulted from marked inflammation involving the wall of the ileum. An extensive operation involving much difficult dissection was necessary in order to remove the involved pelvic organs and to excise completely the fistulous tracts. The closure of the small bowel together with an already existing partial obstruction necessitated an enteroanastomosis.

Case 4* A man, aged 18, came to the clinic on January 22, 1936. Three months previously he had been kicked in the abdomen while playing football. An ab-

This case has been reported in detail elsewhere (Lahay, P. H. and Lium, Rolf. Cure of pancreatic fistula by pancreatojejunostomy. *Surg., Gynec. and Obst.* 64:79-88, 1937).

tous and congested, this process extended to the cecum, and the fistulous tracts communicated with the ileum (Fig 8) A Mikulicz type of resection was done, removing 27 cm. of the ileum, together with the cecum and the ascending colon (Fig 9)

The postoperative course was uneventful. The Mikulicz spur was divided before the patient left the hospital Six weeks later she was readmitted to the hospital and the stoma was closed, 14 days following this closure she was dismissed, with the wound entirely healed.

It is evident that regional ileitis preceded the develop-

Figure 9 Reproduced by courtesy of New York State Journal of Medicine (34 135 1934) Method of resection illustrating the Mikulicz type of resection of the terminal ileum and ascending colon The transverse colon and terminal ileum are brought through the abdominal wound forming the Mikulicz stoma The ileum is staggered so that a drainage tube can be tied within the lumen and immediate drainage of the small bowel obtained

ment of this fistula, perforation occurring after appendectomy had been performed Failure to recognize the condition readily accounts for the unsuccessful attempt at closure The history and examination strongly suggested regional ileitis, and we were fully prepared for the major operative procedure. In cases of regional ileitis a perforation may either occur into adjacent loops of bowel, or produce an external fistulous opening This condition should always be considered as a source of a fistula in the right part of the abdomen. It is obvious that any attempt at extraperitoneal closure of these tracts is doomed to failure. The best results, in our experience, for the control of the ileitis as well as the eradication of the fistula are obtained by resection of the affected loop of bowel In a series of 15 cases of regional ileitis, resection was performed in 9 cases without a death.

In our series of 37 cases of abdominal fistulas, 27 patients were submitted to operation, 5 died after operation, an operative mortality of 19 per cent Ten others were advised to have an operation but refused Of the 27 patients operated on,

permanent closure of the fistula was obtained in 19 (Table 5) Serous material but no fecal contents continued to drain from the fistula in 2 cases in which there was an associated tuberculosis of the pelvic organs Both of these patients were much improved in health following operation

It is of interest to review the pathologic changes in the 5 cases in which death occurred following operation In 1 case peritonitis occurred following an extensive operation for repair of a jejunal

fistula associated with a jejunocolic fistula, which had developed after multiple gastric operations had been performed These cases are serious problems, peritonitis is one of the most dreaded sequelae, and is the cause of death in most instances It occurred in another case after operation for a fistula which had formed after an appendectomy At operation numerous external and internal fistulas were found and an extensive resection of the bowel was necessary Death occurred on the third postoperative day Pneumonia accounted for a fatal outcome in a man of sixty-seven who on admission had had an intestinal obstruction complicating a long-standing fecal drainage Another death followed operation on a patient who had regional ileitis, an ileocolostomy was performed because of his poor condition, but death from inanition resulted three months after operation In the fifth case death occurred at home two months after dismissal from the hospital, at which time the patient apparently was in good condition, the cause of death is unknown

SUMMARY

A study of 37 cases of persistent abdominal fistulas is presented The pathologic condition involved in their production is discussed

The method of determining their origin and the reason for their persistence are outlined Many operations for closure of abdominal fistulas result in failure because the underlying pathologic condition has not been recognized

A general discussion of the principles involved in the surgical treatment is given The operation is a serious one, and in most cases requires extensive technical procedures

Six cases of fistula are reported, together with the operative method employed for the eradication of the fistula in each case

Of 27 patients who submitted to operation, com-

cystic cavity about one fifth the original size. Because of this reduction in size it was decided to pursue a conservative course of treatment. The patient entered the hospital, laboratory studies were made, and medical treatment was instituted. When the patient left the hospital the sinus had shrunk to the diameter of the indwelling catheter. Because pancreatic juice continued to be discharged and because the patient wanted to be rid of the fistula, we decided to transplant the fistula into the jejunum. For 3 weeks before operation the fistula was gradually dilated from the size of a 14 to that of a 22 French catheter.

On March 16, 1936, 5 months after the original accident, a pancreatojejunostomy was done by one of us (F. H. L.). Spinal anesthesia was used. An incision was made around the fistulous tract and the peritoneal cavity was opened about 5 cm. below the opening of the sinus. All layers were dissected through the peritoneum, first to the left and then to the right of the fistula from below. The fistulous tract passed between the stomach and the transverse colon, and was well surrounded by omentum. It was dissected back toward its base about 5 cm., and was cored away until it was only about 1 cm. in diameter. A 22 French catheter was tied into the sinus with silk, to prevent occlusion of the canal after its implantation (Fig. 7). A loop of jejunum was brought up, and with a Babcock clamp on each corner of a rectangular area opposite the mesentery a straight clamp was punctured through the wall of the jejunum. The blades of the clamp were separated, the opening was dilated, and a purse-string suture was placed around this opening and left free. A silk suture was placed on each side of the end of the fistula. These sutures were then brought through the wall of the jejunum and were used to draw the fistula into the jejunum. This maneuver was executed with considerable difficulty. The purse-string suture was then tied, and a row of interrupted catgut sutures was placed between the omental neck of the fistulous tract and the jejunum. Finally a continuous suture was placed between the omentum and jejunum. At the end of the operation the fistulous opening could be felt well within the jejunum, and there was no encroachment on the lumen of the jejunum. The abdomen was closed without drainage, using interrupted silk through and through sutures.

Convalescence was uneventful except for slight sepsis of the wound, which had cleared up entirely by the 12th day after operation. The patient left the hospital in good condition on the 17th day after operation. He has remained well and free from symptoms.

Case 5. A woman, aged 39, entered the clinic on February 16, 1934 because of draining abdominal fistulas. Operation had been performed elsewhere on October 11, 1933, following an attack of pain and tenderness in the left lower part of the abdomen. A perforated diverticulum had been found and apparently resection of the sigmoid flexure with an end-to-end anastomosis had been done. Fecal drainage immediately followed this operation, and on January 12, 1934, an attempt was made elsewhere to close the fistulas, but without success.

Examination revealed three draining fistulas in a left rectus scar. Roentgenologic examination after injection of the fistulous tracts with lipiodol showed that they communicated with the sigmoid flexure of the colon. Examination after a barium enema had been given revealed the presence of numerous diverticula of the colon and a region of narrowing at the level of the fistulous tracts.

In order to divert the intestinal stream, a transverse ileostomy was performed on February 19. Twenty days later the abdomen was opened widely and the fistulous

tracts were excised. A Mikulicz type of resection was necessary to remove the affected part of the sigmoid flexure. Convalescence was uneventful and the wound healed satisfactorily. The stoma in the ileum was closed on May 11, and 13 days later a plastic closure was done on the stoma in the sigmoid flexure. Healing without drainage resulted after 13 days. Examination 6 months after operation showed complete healing, and the patient was in excellent health.

The operation for eradication of fistulas arising in the left portion of the colon is likely to be a highly technical procedure. In most cases resection is required, and occasionally the diverticulosis may be so extensive that the continuity of the bowel cannot be re-established and the patient is left with a permanent colonic stoma. The possibility that a permanent opening will be required should always be considered, and the patient should be so advised before operation is undertaken. Occasionally, if no obstruction is present, the operation may be simple, consisting of an extraperitoneal closure of the openings in the colon and simple excision of the tracts. We have been able to do this in 2 cases in which the fistulas originated from diverticula.

Case 6. A woman, aged 22, was admitted to the clinic on March 3, 1937. Appendectomy with drainage had been done in January, 1935, because of pain and tenderness in the right lower quadrant of the abdomen. Fecal discharge through the appendectomy wound soon followed this op-

Figure 8. The terminal ileum is thickened, edematous and congested. Marked ulceration with almost complete obstruction of the terminal ileum may be noted. This ulcerative process extended to the cecum, and the fistulous tracts communicated with the ileum.

eration, and it had persisted. A second operation was performed 6 months later in an attempt to close the fistula, but without success. The fistula had continued to drain, the patient had lost weight, and had had attacks of vomiting and recurrent pain in the right lower part of the abdomen.

Examination showed an undernourished patient. Two draining fistulas were found which opened into the mid part of an oblique scar in the right lower part of the abdomen. Roentgenologic examination revealed a moderate filling defect in the terminal ileum with mild ileal stasis and distention proximal to this defect. The tentative diagnosis of regional ileitis was made.

Operation was performed April 7, 1937. The old scar with the fistulous opening was excised and the abdomen was opened. The terminal ileum was thickened, edema-

EARLY DIAGNOSIS OF SCHIZOPHRENIA BY THE GENERAL PRACTITIONER

D EWEN CAMERON*

WORCESTER, MASSACHUSETTS

THE difficult problem of the treatment of schizophrenia (*dementia praecox*) has recently aroused considerable attention because of the claims set forth for new therapeutic techniques. In this way facts of pronounced social significance concerning this disease have been brought to light. Outstanding among them is the revelation that most patients suffering from this disorder are brought to hospitals at an astonishingly late stage.

The incidence of schizophrenia is low as compared with that of diseases not directly associated with the brain. Pollock¹ states on the basis of the Federal Census of 1920 that the average annual rate of *dementia praecox* first admissions per 100,000 population during that year was 18.6 for males and 16.4 for females. On the other hand, there is a comparatively low spontaneous remission rate. Fuller² has followed a group of 600 male and 600 female schizophrenics for fifteen years after their first admission. He reports that at the end of that period 38.4 per cent are still in hospitals, 25.0 per cent have died and 36.6 per cent have been discharged. It is to be noted that of the total discharged patients only 12.4 per cent were considered recovered. These figures bring out a condition of great importance, both economic and social, namely, the disease is characterized by a low recovery rate, so that patients tend to accumulate in hospitals. There is also a moderate infiltration of the general population with partially recovered individuals who make a definite contribution to the crime and disease rates, and also to the incidence of problem behavior in children.

The effects of this infiltration cannot at present be computed, but the results of accumulation in hospitals can be. In the Massachusetts state hospitals in 1936 schizophrenics comprised 15.9 per cent of total first admissions, while they accounted for 39.0 per cent of the first-admission resident hospital population. Similarly, during that year only 23.1 per cent of the patients readmitted to hospitals were schizophrenic, but 62.3 per cent of hospital residents who had been readmitted were so diagnosed.

On September 30, 1936 the total number of schizophrenic patients in the Massachusetts state hospitals was 12,212. The per capita cost was estimated at \$775 per week. Consequently the direct annual cost of these patients, leaving out of ac-

count the loss in earning power, amounted to approximately \$5,000,000.³

The incidence of schizophrenia in the general population will be shown more vividly if we realize that it first begins to appear at the approach of puberty. From then on the curve soars rapidly to reach its crest at about the thirtieth year. It then subsides gradually until the fiftieth year, after which practically no cases appear. Furthermore, the incidence among the rural population is much less than that among city-dwellers. Pollock and Nolan⁴ report that this rate in the urban population of New York State from 1915 to 1920 was 19.1 per 100,000 population, while in the rural communities it was 7.8. There is a slight tendency, represented by the ratio 113:100, for schizophrenia to appear in men more frequently than in women.

Reducing these figures to terms of everyday experience, one may expect that most of these patients will come to the general practitioner not from schools but from factories, stores, universities, transportation services, the professions, and other fields of work in which young men and women begin their careers. A fair number of cases will follow the first few pregnancies and so occur during early married life. A limited number of patients will come from farms and from groups in other outdoor occupations.

The influence of heredity is extremely difficult to gauge. It is still unusual to find reliable records for several generations, and it is almost impossible to ascertain whether abnormalities in the offsprings of schizophrenics are due to inheritance or to the environment created by the parents. There is, however, general agreement that from the point of view of the healthy development of children such environments are undesirable.

RELATION OF DURATION OF ILLNESS TO THERAPEUTIC RESULTS

The therapeutic attack waged for decades on this disease has been active but relatively unsuccessful. Procedures have recently been developed for which much is claimed. Proof of such claims is still lacking, and their validation has been made even more difficult because a considerable number of schizophrenic patients come to hospitals late, as a result, their condition is relatively hopeless and comparable to that in cancer after metastases have developed, or to that in pulmonary tuberculosis after cavitation.

Senior research physician, Worcester State Hospital.

plete closure was obtained in 19. Any operation designed to eradicate these fistulas is likely to be extensive, and because of this carries with it a high mortality (19 per cent).

DISCUSSION

DR LAHEY. There are two or three important points to emphasize in connection with this paper. One is the value of the button method. We did not originate this idea. I found it somewhere in the earlier literature. If you have not employed buttons, you will do well to remember that they will save lives in occasional cases of duodenal or jejunal fistula. We now have a patient who had a gastroenterostomy, then a gastrojejunal ulcer, which was removed. He then had a jejunostomy, and following the establishment of a jejunal fistula he lost weight at the rate of about 1 lb a day. We were in despair as to how to save his life, because he was losing weight so rapidly that we could not think of operating. We split the sinus tract, introduced an ordinary bone button on edge with a silver wire threaded into its holes, put another button on top, and brought them together by twisting the silver wire. This controlled the fistula well enough so that the patient immediately began to regain his weight. At the end of two weeks we cut the wire and let the button pass, and the fistula immediately closed. Several times buttons have saved our patients' lives.

Another matter that I wish to stress is regional ileitis. This paper has, I think, covered all the points regarding fistulas, but I urge that everyone keep in mind the question of regional ileitis. It is occurring constantly. When this paper was first begun, we had had only 15 cases, we have now had 23. I did a resection in such a case day before yesterday. The history is so typical in most of the cases that we should not make many mistakes in diagnosis, nor should we delay until the typical roentgenologic findings of a rigid terminal ileum are found.

Most of these patients have had repeated attacks of pain, usually resembling those of appendicitis. Many have had their appendices removed, but the trouble still continues. The history is one of right sided pain, often with colic and fever, and usually associated with attacks of diarrhea. Late in the disease, the ileum shows definite stiffening, but early it may not be easy to bring out the typical roentgenologic picture of ileitis. Certainly in all the patients who have so-called appendiceal symptoms associated with diarrhea, particularly with each attack, we should consider regional ileitis. Conservative operations for this condition are unwise. They leave the lesion untouched, they permit feces to run through the incompletely obstructed segments, and they tend to produce secondary fistulas. We have performed resections in 15 cases, with no mortality and with excellent results. In the cases in which a lateral anastomosis was made, complications occurred, and there tended to be fistulas into the other segments of the bowel, so that this procedure seems unsatisfactory.

DR H. GILDERSLEEVE JARVIS, Hartford, Connecticut. As regards duodenal and biliary fistulas, we have had 2 cases

sent to us for operation. These patients had had a continuous fistula since their original operation. Each fistula was thought to have been caused by severance of the common duct. In both cases, however, operation revealed a stone in the common duct just distal to the cystic duct, and its removal caused the fistula to clear up entirely. If the common duct has been cut, exploration of the fistula frequently reveals the condition, and at some future operation the ends can be rejoined.

In abdominal fistulas that arise from the gall bladder or the intestinal tract, the first thing to determine is where they originate. We had 1 case in which an abdominal fistula arose from the appendix and came to the surface in the right renal region. The removal of the appendix effected a complete cure.

DR ERNEST M DALAND, Boston. A case of actinomycosis of the large bowel with persistent fistulas came under our care last year at the Massachusetts General Hospital, the patient was a girl of sixteen who had been operated on two years previously for a ruptured appendix. Following this she had had a persistent fistula. A second operation had been done, following which there were two fistulas. There was a third operation, and when we saw her, about 2 years after the first operation, she had five or six fistulas. We examined the pus from the discharge and inoculated guinea pigs with it, but could find no organisms. We made a special search for actinomycetes. The patient developed a subphrenic abscess and a psoas abscess, both of which we drained successfully. The sinuses persisted, and all connected with the psoas space. We then did an anastomosis of the ileum and transverse colon, with some improvement, and the girl was sent home. She returned with a persisting fistula, whereupon a right-sided colectomy was done. In the specimen, the pathologist found one area of actinomycosis, which was the basis of the final diagnosis. After the colectomy the patient did quite well for two weeks, then the blind end of the transverse colon opened and there was again drainage through the psoas wound. We administered large quantities of iodides, and improvement began. Two weeks later she developed an acute obstruction, and in spite of all we could do, she died. No autopsy was obtained.

DR MARSHALL. It is worth noting that most of the cases we have reported were referred to us after several attempts had been made to close the fistulous tract. We must recognize the underlying lesion if we are to be successful in the management of these cases. Extraperitoneal operations will rarely accomplish closure of this type of fistula. This is particularly true of fistulas arising from the sigmoid as the result of a perforated diverticulum. These patients must be warned that operation may be difficult, and in many instances must be told they may be left with a permanent colonic stoma. The reason for the latter is that frequently in the eradication of the fistula and the accompanying lesion for relief of the obstruction, it may be necessary to remove so much of the sigmoid that re-establishment of the intestinal canal cannot be done.

his ambition and his interest in life Rosanoff¹³ refers particularly to lack of interest, and to the slothfulness with which friends and relatives often charge the patient. The failure in capacity in some cases is not of the general nature just described, but is revealed in periodic exhibits of poor judgment and in inability to grasp situations.

Emotional Dulling The majority of investigators of the early symptoms of schizophrenia lay considerable stress on emotional disturbances. These are predominantly of the nature of dulling, though occasionally moodiness or outbursts of irritability may be present. The dulling may show itself simply as part of the syndrome already mentioned under withdrawal. The patient appears to be quite uninterested in what is going on, even matters of great importance may serve to arouse no interest, or a mere show of interest. A further aspect is the relative inscrutability which such patients present to the observers. It is exceptionally difficult to feel in tune with them, for not only have ordinary daily events lost their significance, but matters which seem trivial to the average person begin to acquire special meanings and special emotional importance for the patient. Kretschmer says aptly that it is as though a sheet of glass stood between the observer and the patient. This simile is capable of further extension, for not only is it difficult for the observer to feel in touch with the patient, but it is apparently no less difficult for the patient to keep himself in emotional rapport. Indeed, this symptom may first become conspicuous through the patient's revealing, contrary to his usual custom, occasional unfeeling and callous behavior in dealings with his friends. Maver-Gross¹⁴ has given an excellent description of this gradual loss of the finer sensibilities.

Tendency to Misinterpretation This symptom usually appears rather later than the former three and may be the precursor of definite delusions. In the early stages, however, the patient may, for example, simply have a feeling that people are looking at him or talking about him. The impression may at first be quite transitory, and the patient may either spontaneously or on reassurance realize that he is in error. This feeling that people are not friendly to him or are paying special attention to him may disappear when the patient goes to a new locality, and not recur for several months. Occasionally one encounters patients who for this reason and because their illness has developed slowly, have for years moved from place to place across the country finding a few weeks or months respite in each fresh environment. The tendency to misinterpret may also show itself in other spheres than that of personal relation, for instance, the patient may grow suspicious as to the

purity of his food. At first these symptoms are all on an "as if" basis, the patient claiming that the food tastes as if it were not wholesome, or as if it had been contaminated by some foreign substance.

Less Common Early Symptoms Occasionally, first complaints relate to difficulties in thinking. Difficulty in concentration has already been referred to. A less common symptom is a feeling that the patient's thoughts have suddenly vanished, so that he is unable to carry on a line of thought. Patients sometimes speak of the intrusion of thoughts which seem to them to be absurd and irritating, but which are later placidly accepted. During the early stages of this development, care must be taken to distinguish this symptom from the obsessional neurosis, as described below under differential diagnosis.

A second group of less frequent symptoms is comprised of various physical ailments. As a rule these refer either to a general feeling of weakness and easy fatigability, or to rather odd or persistent complaints in the absence of physical symptoms to substantiate them. In particular the heart, the stomach, the functions of excretion and the reproductive apparatus are singled out. As the illness progresses the complaints become more and more fixed and bizarre, so that a patient who has been concerned over alleged palpitation and weakness of his heart may declare that his heart has stopped entirely or has been transferred to the right side of his body. A final symptom, which is only infrequently found in early stages, is a sensation of unreality, the patient complains that he feels as though he were in a dream, that he does not feel normal, and that things around him, although well known to him, have lost the touch of familiarity. This symptom, when it does occur early, usually portends the rapid development of the disease.

DIFFERENTIAL DIAGNOSIS

Although the presence of any of the symptoms outlined should arouse suspicion, final diagnosis must be based on the detailed picture presented by the patient. In the early stages of schizophrenia care must be taken to distinguish it from conditions with which in its later development there would be no danger of confusion. Brain tumors, especially those located in the frontal lobes, may present a picture difficult to distinguish from that of early schizophrenia, save after an exhaustive neurological examination. Similarly, the late and gradual development of a postencephalic Parkinsonian syndrome may, during its first stages, imitate the symptoms of early schizophrenia. This syndrome is particularly confusing when it occurs in association with personality changes in adolescence. A detailed history will usually serve to bring to light

During the last several years one therapeutic method after another has been proposed, in each instance it has been emphasized that considerably better results have been obtained in early cases. The production of long-continued sleep, introduced by Klati⁵ and since modified by many workers, is reported by Favre⁶ to have little success in cases of long standing. Meduna,⁷ who recently brought out a method of treatment whereby convulsions were produced through the intravenous injection of metrazol, states that the first six months of the disease constitute by far the most favorable period, this is borne out by Friedman,⁸ who introduced the method in this country. Sakel,⁹ and the numerous workers who have used his treatment, consisting in the production of insulin hypoglycemia, have emphasized that there is a close relation between the duration of the illness and the outcome of the treatment. Good results are claimed when the cases are of less than six months' duration. The outlook is still hopeful when the duration is less than eighteen months, but thereafter the likelihood of a favorable outcome rapidly lessens. Dussik¹⁰ in a recent article even insists that delay within the first six months in itself renders the treatment more difficult and the outlook more dubious.

PRESENT STATUS OF SCHIZOPHRENIA ADMISSIONS

Those who are developing new methods of treatment in Massachusetts state hospitals generally agree that the great majority of patients who might have benefited come to the hospital in an advanced stage of illness. Hospital records have repeatedly shown that individuals have been clearly recognized as mentally sick even by laymen for years before hospital treatment was sought. From March, 1936, to February, 1937 (inclusive), 197 cases of schizophrenia were admitted to the Worcester State Hospital. Of these, 32.4 per cent had shown symptoms for six months or less, 17.5 per cent for between six months and two years, and 48.1 per cent for over two years. This delay in hospitalization is also clearly shown by the following figures, based on first admissions to the New York Civil State Hospital¹ in 1925:

AGE GROUP	AVERAGE DURATION OF SYMPTOMS BEFORE ADMISSION (YEARS)
15-19	7
20-24	1.5
25-29	1.7
30-34	2.0
35-39	2.7

The delay is partly due to the reluctance of families to have their members enter a state hospital, it is also partly due to the obstacles to early diagnosis, and to the difficulty experienced by the

general practitioner in obtaining a clear picture of the early symptomatology.

EARLY SYMPTOMS

Early symptoms vary to some extent with the age at which the disorder begins. In the younger age groups there are two fairly well-divided trends. One is the gradual development of schizophrenia in a person who has from childhood been an odd, aloof individual, or one who has shown many behavior problems, such as long-continued enuresis, temper tantrums, sulking and emotional instability. There is frequently a gradual accentuation of personality trends for years, the first recognition of the illness coming with the appearance of frank delusions. The second trend is the sudden appearance of odd, perhaps dramatic, behavior in a person who has been under recent stress. It may take many forms: stupor, or states of ecstasy, or suicidal attempts, or bizarre exhibitionism. Infantile traits, such as bed-wetting and refusal to eat unless actually fed, may appear. Usually accompanying this condition are considerable confusion and inability to concentrate. In the older age groups the onset is often more insidious. Four groups of early symptoms require special notice: withdrawal, loss of capacity, emotional dulling, and tendency toward misinterpretation.

Withdrawal. In this condition, the patient who may hitherto have enjoyed good social relations, both at home and in his work, gradually becomes less approachable. His family observe that he goes out less frequently, no new friends are made, and old acquaintances are gradually dropped. The patient appears to become dull, his social relations lose some of their warmth. Interests and hobbies claim his attention to a decreasing degree, and he spends a considerable part of his time in daydreaming. Occasionally the patient makes active efforts to secure solitude. Even less frequently he realizes that he is drifting away from contact with every day affairs, and tries hard to recover his old ability to be interested and to form friendships. Noyes¹¹ states that in the patient who is "usually poorly endowed in warmth and spontaneity there is a decrease both in desire and attempts to express the personality." Yellowlees¹² lays great stress upon withdrawal from reality, and believes that this symptom will be found in almost every adequately studied case of schizophrenia.

Loss of Capacity. Among the earlier symptoms is a gradual failure to deal with everyday tasks of work and living. This, too, may be recognized by the patient, and he may complain that he has lost the capacity to concentrate or that he has lost his former energy. More often his friends first comment upon it and refer to his having lost

SOCIAL SECURITY AND THE PHYSICIAN

CHARLES A SPARROW, M.D.*

WORCESTER, MASSACHUSETTS

THE scope of the term "social security" is almost unlimited, hence, in considering the problem we should divorce our minds from the meager provisions of the Social Security Act approved August 14, 1935. The subject is much broader. President Roosevelt has summed it up well by saying, "Among our objectives I place the security of the men, women and children of the nation first." He has also said that security for the individual and for the family concerns itself with three factors: (1) decent homes to live in, (2) development of the natural resources of the country so as to afford the fullest opportunity to engage in productive work, and (3) safeguards against the major misfortunes.† My discussion, however, will be confined to those aspects of social security which impinge on the life and work of the physician.

Until today, this country has lagged far behind many others in social security legislation, but now that a beginning has been made we will, whether we wish to or not, be forced rapidly onward by reason of the ever-accelerating speed with which social rules are gathering headway in our democracy. From now on, the medical profession in all its contacts with the public will become increasingly aware of the new conditions brought about by social legislation, and be forced to adjust itself to them. We may wish with all our hearts that we could go back to the horse-and-buggy days, after all, those times had something to recommend them, but, as we have recently been so constantly reminded, those days are gone forever. We must either keep up with the march of time or be left jogging along behind. Far too many of us doctors go about our practice without realizing that while we are attending conscientiously to the task of the moment, grave issues of medical policy are every day pressing closer. In our medical journals, newspapers and magazines we read of the trend toward state medicine, the entrance of government into the care of tuberculosis, cancer, pneumonia, and so forth. But do we actively concern ourselves with the legislation, the setting up of commissions, the financing and the centers of control of these new governmental interests? We owe to ourselves, to our community, to the state and to the nation, an intelligent understanding of social security. Not only that, as doctors and as members of this medi-

cal society we should define in our minds our share in this field of medicine. For instance, it seems to be generally agreed that the bona-fide indigent should be cared for by some governmental agency. Should we not be ready to declare our stand on the methods to be employed? Should we not have a plan for improving the health of the nation by the extension of preventive medicine? Should we not formulate plans or at least a theory for financing the care of the indigent? In addition, should we not make recommendations as to where the control of this work should lie? These matters, it seems to me, are the vital concern of every one of us.

For centuries workers sought protection against sickness and its concomitant wage loss through the medieval guilds, the trade unions and a variety of mutual-aid societies. Before the industrial revolution many of the uncertainties and calamities of life were due to natural causes. With the coming of the machine age and the urbanization of populations, new uncertainties appeared, large classes of people who were without property and were earning small wages found themselves unable to meet many of the emergencies that arose. They banded together and pooled their resources, and many employers organized welfare and relief schemes.

Up to the last years of the nineteenth century, governments followed a hands-off policy. The states first encouraged mutual aid by authorizing welfare schemes and regulating contracts. The movement has in the last fifty years brought to birth thousands of mutual-aid institutions in many countries, with a total membership counted in the millions, yet in all this time only a small proportion of the working class has been enrolled. In particular those earning low wages did not join these societies, which despite their large numbers were individually quite small, they were also very unevenly distributed, being numerous in the cities and almost non-existent in rural areas.

In spite of its theoretical advantages, voluntary insurance was not sufficient, compulsory insurance was the next step taken to provide wider aid and better protection. Germany in 1883 under Bismarck, without any effective experimentation with the voluntary method, was the first to make insurance compulsory for industrial workers, in 1885 the scheme was extended to commerce and in 1886 to agriculture, so that from 40 to 45 per cent of the population of Germany is now covered by

the earlier acute illness. Other organic conditions which require consideration are epilepsy, where the attacks are light and unobserved and the changes in personality well developed, drug addiction, especially alcoholism, and the toxic states. In general the symptoms peculiar to these conditions will serve as counterpoises in the observer's judgment against those also exhibited in early schizophrenia. Mayer-Gross,¹⁴ in considering the differential diagnosis of schizophrenia and the organic affections of the central nervous system, lays stress first on the physical symptoms which accompany the latter, secondly on the fact that, while in this group the intelligence and memory are usually more affected than are the quality of emotional responses and the ability to establish emotional rapport, in the schizophrenic the reverse is the rule.

Among the mental conditions, the disorder which is most likely to cause confusion is manic-depressive psychosis. Henderson and Gillespie¹⁵ point out that the apathy, the listlessness, and in fully developed cases, the stupor of schizophrenia may be confused with those manifested by depression. They emphasize that, as even brief inquiry usually reveals, the listless schizophrenic has no feeling of sadness, but is often contented and desires only to be let alone. Certain psychoneuroses, particularly obsessional neurosis, and to a lesser extent hysteria, present some difficulties, the former because of the occurrence of intrusive thoughts which the patient cannot control, and the latter because of the occasional inadequate emotional responses and of the trance-like states which may cause confusion with the true catatonic stupor. The diagnosis must be made on the detailed picture presented by the early symptoms, with no one of them overstressed.

SUMMARY

The social and economic significance of schizophrenia has been demonstrated. Although the illness is one with a relatively low incidence it has great chronicity, so that ultimately more hospital beds are occupied by schizophrenic patients than

by patients suffering from any other mental illness. The financial burden which this disease imposes is heavy. A significant feature is that the average patient is brought to the hospital relatively late in his illness. In many cases, when hospital treatment is begun, symptoms have been present for years. Hospital treatment has in the past offered little more hope for early cases than has care in the home. Recently, however, various forms of treatment have been brought forward, their originators and proponents emphasizing that they are much more effective in the early stages. The value of these methods has not yet been fully assessed. These conditions, and the general experience of physicians that the earlier in the disease treatment is begun, the better chance it has of proving effective, lead inevitably, however, to one conclusion—every effort must be made to promote earlier hospitalization. Since this responsibility rests chiefly on the general practitioner, we have endeavored to give a description of the earliest symptoms of which we have knowledge.

3A Grants to States for Maternal and Child Welfare (Title V, Part 1) The purpose of this act is "to extend and improve as far as practicable under the conditions in such a state services for promoting the health of mothers and children, especially in rural areas suffering from severe economic distress" For this the act authorizes the annual appropriation of \$3,800,000 The federal administrative agency is the Children's Bureau of the Department of Labor, which agency dictates the policy As this bureau is under the direction of social welfare workers, its policy is naturally more influenced by their conception of social welfare expediency than by medical necessity The bureau holds the purse string for the states, since all grants must be approved by it If so approved each state gets \$20,000 and such proportion of \$1,800,000 as live births in that state bear to the total live births in the United States, and \$980,000 distributed on the basis of need, again taking into consideration the number of live births in the state Except for the latter distribution each state appropriates an amount of money equal to the federal payment Up to April 28, 1936, thirty-nine states and Alaska, the District of Columbia and Hawaii had qualified for federal grants All state plans are aimed primarily at the education of doctors, nurses, parents and children in the care of the health of the mother and child Several states are conducting demonstrations in a special effort to reduce maternal mortality, through maternal-health education, obstetric service for examination and consultation, and nursing service for prenatal, delivery and postpartum care In Arizona a mobile tuberculosis unit gives diagnostic and advisory services to referred children

3B Services for Crippled Children (Title V, Part 2) This part of the act is intended to enable each state "to extend and improve, especially in rural areas and in areas suffering from severe economic distress, services for locating crippled children and for providing medical, surgical, corrective and other services and care and facilities for diagnosis, hospitalization and after care for children who are crippled or who are suffering from conditions which lead to crippling" An annual appropriation of \$2,850,000 is provided Again, the Children's Bureau dictates policy and controls administration The language of the act is vague, and just what the services mentioned above will consist of depends entirely on the discretion of the bureau Each state having a plan appropriate to the indicated service and approved by the Children's Bureau receives \$20,000 annually, the remaining \$1,830,000 to be distributed "to the states according to the need of each state as determined after taking into consideration the number of

crippled children in such state in need of services" The cost of furnishing such services to the states favored with allotments must be matched by them, dollar for dollar A year ago many states had no official agency for providing services to crippled children as a recognized public responsibility There are now such official agencies in forty-six states, up to June, 1936, in twenty-nine of these states the agencies had been approved by the Children's Bureau This section of the act will certainly develop state-wide programs of services to crippled children, although sundry agencies will administer them Co-operation with the vocational rehabilitation services of the state concerned is required

3C Child-Welfare Service (Title V, Part 3) The act is to enable the United States to co-operate with the states in establishing, extending and strengthening in predominately rural areas child-welfare services for the protection and care of homeless dependent and neglected children in danger of becoming delinquent" Ten thousand dollars goes to each state, and \$996,000 is distributed annually among the states No provision is made for the states' obligations to match these sums This part of the act is also directed by the Children's Bureau

5 Vocational Rehabilitation (Title V, Part 4) This measure authorizes the appropriation of \$1,841,000 for 1936-1937, and thereafter \$1,938,000 annually, to the states in order to extend and strengthen the program of vocational rehabilitation of the physically disabled Each state is to receive, after \$5000 goes to Hawaii, such proportion of this sum as its population bears to the population of the United States, no state to get less than \$10,000, and each state to match this grant, dollar for dollar

6 Public-Health Services (Title VI) This section authorizes an annual federal appropriation of \$8,000,000, to be distributed among the states in order to assist "states, counties, health districts and other political subdivisions of the state in establishing and maintaining adequate public-health services, including the training of personnel for state and local health work" This money is distributed on the basis of (1) population, (2) special health needs and (3) financial needs The federal administrative agent is the Surgeon General of the United States Public Health Service, and he must approve all plans before any state can receive a grant There is also provision for an annual appropriation of \$2,000,000 to the United States Public Health Service, to be used for "investigations of diseases and problems of sanitation and for the pay and allowance and traveling expenses of personnel of the Public Health Service

this plan. In Great Britain 39 per cent is thus taken care of. Austria and Hungary entered the field of compulsory insurance between 1888 and 1891. With the beginning of the twentieth century many other countries, among them Luxembourg in 1901, Norway in 1909, Serbia in 1910, Great Britain and Russia in 1911 and Rumania in 1912, did so, at the present time twenty-nine countries have compulsory insurance.

Our first attempt to follow this system was the enforcement of insurance through the Workmen's Compensation Act. Because of public indignation, and under the forceful leadership of President Theodore Roosevelt, the first workmen's compensation law was passed by Congress in 1908, to cover laborers under federal jurisdiction. In 1911 ten states passed similar laws, by 1916 thirty-one states had compensation insurance, and in 1936 only two states, Arkansas and Mississippi, were without such laws.

As might have been predicted from the experience of Europe, the medical profession remained aloof and largely indifferent and uninformed. The laws were for the most part framed without benefit of medical counsel, and their administration was placed almost exclusively in lay hands, until 1934 only one state had a physician on its compensation commission. The New York State law, effective July 1, 1935, gives to physicians one third of the representation on the Industrial Council, which is charged with a broad advisory function in the administration of workmen's compensation.

The difficulties encountered by European nations have been repeated in a small degree in the United States. Blunders in administrative organization, excessive lay control of professional practice, inadequate medical service, unfair remuneration of medical practitioners, excessive costs and wasteful management, exploitation of commercial insurance carriers, malingerers by workmen, frauds by physicians, shyster practices by lawyers, are all on record.

Our experience in workmen's compensation is well summarized by I. S. Falk. His conclusions are as follows:

(1) The scope of the compensation law has broadened by extending the coverage to larger numbers and varieties of industries by embracing (in twelve states) occupational diseases along with industrial accidents, by expanding the variety and by increasing the duration of medical service.

(2) The emphasis has to an increasing degree been shifting from the provision of cash benefits (to replace wage loss and for the purchase of medical care) to furnishing benefits in kind (medical care as a supplement to cash benefits for wage loss) although cash benefits still consume approximately twice as much money as do medical benefits.

(3) The worst evils in compensation medical practice in connection with the workmen's compensation act may be traced to lack of adequate professional participation in formulating and administering the laws. Some of the

most serious abuses have been eliminated where joint medical and lay groups have arrived at agreements upon revised procedures.

Our next attempt to extend the principle of social security was the Social Security Act, placed on the statute books in August, 1935. This act was devised to provide some safeguard against the insecurity of modern life through co-operative action by the federal and state governments, thus making possible the fullest consideration of local economic and social problems while maintaining a national unity of program. President Roosevelt, at the National Conference on Economic Security in November, 1934, said in part:

There is also the problem of economic loss due to sickness, a very serious matter for many families with and without income, and therefore an unfair burden upon the medical profession. Whether we come to this form of insurance sooner or later on, I am confident that we can devise a system which will enhance and not hinder the remarkable progress that has been made and is being made in the practice of medicine and surgery.

At this same conference Secretary of Labor Perkins said:

Ill health is a hazard which may strike at any age, and is rendered particularly distressing by the economic considerations that are involved. Through its Public Health Service the Government has for a long time accepted a certain measure of responsibility for the health of the people. That service by its preventive and educational work has played an increasingly valuable part in improving the Nation. But we cannot shut our eyes to the fact that vast numbers of our people in times of sickness are unable to pay the costs of necessary medical care. From time immemorial the members of the medical profession have cared for the needy without thought of reward. We cannot in fairness ask them to carry a burden which under the stress of modern conditions becomes heavier daily. Our problem is to bring adequate medical care within the reach of those who cannot at present afford it and at the same time safeguard the highest interest of the profession, which has always given without stint of its service to the care of suffering and needy humanity. To this end the co-operation of the medical profession is vital and I have every confidence that such co-operation will be accorded by the profession, which has always had such fine traditions of public service.

It appears from these two statements that the medical profession is still held in high esteem by the President and the Secretary of Labor.

The Social Security Act includes a number of distinct though related measures, which may be grouped under the following headings:

- 1 Unemployment compensation
- 2 Old-age assistance and old age benefits.
- 3 Security for mothers and children
- 4 Aid to the blind
- 5 Vocational rehabilitation
- 6 Extension of public health services

We are not directly concerned with the first two and the fourth headings, but the others require some explanation.

3A Grants to States for Maternal and Child Welfare (Title V, Part 1) The purpose of this act is "to extend and improve as far as practicable under the conditions in such a state services for promoting the health of mothers and children, especially in rural areas suffering from severe economic distress" For this the act authorizes the annual appropriation of \$3,800,000 The federal administrative agency is the Children's Bureau of the Department of Labor, which agency dictates the policy As this bureau is under the direction of social welfare workers, its policy is naturally more influenced by their conception of social welfare expediency than by medical necessity The bureau holds the purse string for the states, since all grants must be approved by it If so approved each state gets \$20,000 and such proportion of \$1,800,000 as live births in that state bear to the total live births in the United States and \$980,000 distributed on the basis of need, again taking into consideration the number of live births in the state Except for the latter distribution each state appropriates an amount of money equal to the federal payment Up to April 28, 1936, thirty nine states and Alaska, the District of Columbia and Hawaii had qualified for federal grants All state plans are aimed primarily at the education of doctors, nurses, parents and children in the care of the health of the mother and child Several states are conducting demonstrations in a special effort to reduce maternal mortality, through maternal-health education, obstetric service for examination and consultation, and nursing service for prenatal, delivery and postpartum care In Arizona a mobile tuberculosis unit gives diagnostic and advisory services to referred children

3B Services for Crippled Children (Title V, Part 2) This part of the act is intended to enable each state "to extend and improve, especially in rural areas and in areas suffering from severe economic distress, services for locating crippled children and for providing medical, surgical, corrective and other services and care and facilities for diagnosis, hospitalization and after care for children who are crippled or who are suffering from conditions which lead to crippling" An annual appropriation of \$2,850,000 is provided Again, the Children's Bureau dictates policy and controls administration The language of the act is vague, and just what the services mentioned above will consist of depends entirely on the discretion of the bureau Each state having a plan appropriate to the indicated service and approved by the Children's Bureau receives \$20,000 annually, the remaining \$1,830,000 to be distributed "to the states according to the need of each state as determined after taking into consideration the number of

crippled children in such state in need of services' The cost of furnishing such services to the states favored with allotments must be matched by them, dollar for dollar A year ago many states had no official agency for providing services to crippled children as a recognized public responsibility There are now such official agencies in forty six states, up to June, 1936, in twenty-nine of these states the agencies had been approved by the Children's Bureau This section of the act will certainly develop state-wide programs of services to crippled children, although sundry agencies will administer them Co-operation with the vocational rehabilitation services of the state concerned is required

3C Child-Welfare Service (Title V, Part 3) The act is to enable the United States to co-operate with the states in establishing, extending and strengthening in predominately rural areas child-welfare services "for the protection and care of homeless dependent and neglected children in danger of becoming delinquent" Ten thousand dollars goes to each state, and \$996,000 is distributed annually among the states No provision is made for the states' obligations to match these sums This part of the act is also directed by the Children's Bureau

5 Vocational Rehabilitation (Title V, Part 4) This measure authorizes the appropriation of \$1,841,000 for 1936-1937, and thereafter \$1,938,000 annually, to the states in order to extend and strengthen the program of vocational rehabilitation of the physically disabled Each state is to receive, after \$5000 goes to Hawaii, such proportion of this sum as its population bears to the population of the United States, no state to get less than \$10,000, and each state to match this grant, dollar for dollar

6 Public-Health Services (Title VI) This section authorizes an annual federal appropriation of \$8,000,000, to be distributed among the states in order to assist "states, counties, health districts and other political subdivisions of the state in establishing and maintaining adequate public-health services, including the training of personnel for state and local health work" This money is distributed on the basis of (1) population, (2) special health needs and (3) financial needs The federal administrative agent is the Surgeon General of the United States Public Health Service, and he must approve all plans before any state can receive a grant There is also provision for an annual appropriation of \$2,000,000 to the United States Public Health Service, to be used for "investigations of diseases and problems of sanitation and for the pay and allowance and traveling expenses of personnel of the Public Health Service

this plan. In Great Britain 39 per cent is thus taken care of. Austria and Hungary entered the field of compulsory insurance between 1888 and 1891. With the beginning of the twentieth century many other countries, among them Luxembourg in 1901, Norway in 1909, Serbia in 1910, Great Britain and Russia in 1911 and Rumania in 1912, did so, at the present time twenty nine countries have compulsory insurance.

Our first attempt to follow this system was the enforcement of insurance through the Workmen's Compensation Act. Because of public indignation, and under the forceful leadership of President Theodore Roosevelt, the first workmen's compensation law was passed by Congress in 1908, to cover laborers under federal jurisdiction. In 1911 ten states passed similar laws, by 1916 thirty-one states had compensation insurance, and in 1936 only two states, Arkansas and Mississippi, were without such laws.

As might have been predicted from the experience of Europe, the medical profession remained aloof and largely indifferent and uninformed. The laws were for the most part framed without benefit of medical counsel, and their administration was placed almost exclusively in lay hands, until 1934 only one state had a physician on its compensation commission. The New York State law, effective July 1, 1935, gives to physicians one third of the representation on the Industrial Council, which is charged with a broad advisory function in the administration of workmen's compensation.

The difficulties encountered by European nations have been repeated in a small degree in the United States. Blunders in administrative organization, excessive lay control of professional practice, inadequate medical service, unfair remuneration of medical practitioners, excessive costs and wasteful management, exploitation of commercial insurance carriers, malingering by workmen, frauds by physicians, shyster practices by lawyers, are all on record.

Our experience in workmen's compensation is well summarized by I. S. Falk. His conclusions are as follows:

(1) The scope of the compensation law has broadened by extending the coverage to larger numbers and varieties of industries by embracing (in twelve states) occupational diseases along with industrial accidents, by expanding the variety and by increasing the duration of medical service.

(2) The emphasis has to an increasing degree been shifting from the provision of cash benefits (to replace wage loss and for the purchase of medical care) to furnishing benefits in kind (medical care as a supplement to cash benefits for wage loss) although cash benefits still consume approximately twice as much money as do medical benefits.

(3) The worst evils in compensation medical practice in connection with the workmen's compensation act may be traced to lack of adequate professional participation in formulating and administering the laws. Some of the

most serious abuses have been eliminated where joint medical and lay groups have arrived at agreements upon revised procedures.

Our next attempt to extend the principle of social security was the Social Security Act, placed on the statute books in August, 1935. This act was devised to provide some safeguard against the insecurity of modern life through co-operative action by the federal and state governments, thus making possible the fullest consideration of local economic and social problems while maintaining a national unity of program. President Roosevelt, at the National Conference on Economic Security in November, 1934, said in part:

There is also the problem of economic loss due to sickness, a very serious matter for many families with and without income, and therefore an unfair burden upon the medical profession. Whether we come to this form of insurance sooner or later on, I am confident that we can devise a system which will enhance and not hinder the remarkable progress that has been made and is being made in the practice of medicine and surgery.

At this same conference Secretary of Labor Perkins said:

Ill health is a hazard which may strike at any age, and is rendered particularly distressing by the economic considerations that are involved. Through its Public Health Service the Government has for a long time accepted a certain measure of responsibility for the health of the people. That service by its preventive and educational work has played an increasingly valuable part in improving the Nation. But we cannot shut our eyes to the fact that vast numbers of our people in times of sickness are unable to pay the costs of necessary medical care. From time immemorial the members of the medical profession have cared for the needy without thought of reward. We cannot in fairness ask them to carry a burden which under the stress of modern conditions becomes heavier daily. Our problem is to bring adequate medical care within the reach of those who cannot at present afford it, and at the same time safeguard the highest interest of the profession, which has always given without stint of its service to the care of suffering and needy humanity. To this end the co-operation of the medical profession is vital, and I have every confidence that such co-operation will be accorded by the profession, which has always had such fine traditions of public service.

It appears from these two statements that the medical profession is still held in high esteem by the President and the Secretary of Labor.

The Social Security Act includes a number of distinct though related measures, which may be grouped under the following headings:

- 1 Unemployment compensation
- 2 Old-age assistance and old age benefits
- 3 Security for mothers and children
- 4 Aid to the blind
- 5 Vocational rehabilitation
- 6 Extension of public health services

We are not directly concerned with the first two and the fourth headings, but the others require some explanation.

3A Grants to States for Maternal and Child Welfare (Title V, Part 1) The purpose of this act is "to extend and improve as far as practicable under the conditions in such a state services for promoting the health of mothers and children especially in rural areas suffering from severe economic distress" For this the act authorizes the annual appropriation of \$3,500,000 The federal administrative agency is the Children's Bureau of the Department of Labor, which agency dictates the policy As this bureau is under the direction of social welfare workers, its policy is naturally more influenced by their conception of social welfare expediency than by medical necessity The bureau holds the purse string for the states, since all grants must be approved by it If so approved each state gets \$20,000 and such proportion of \$1,800,000 as live births in that state bear to the total live births in the United States and \$950,000 distributed on the basis of need, again taking into consideration the number of live births in the state Except for the latter distribution each state appropriates an amount of money equal to the federal payment Up to April 28, 1936, thirty-nine states and Alaska, the District of Columbia and Hawaii had qualified for federal grants All state plans are aimed primarily at the education of doctors, nurses, parents and children in the care of the health of the mother and child Several states are conducting demonstrations in a special effort to reduce maternal mortality, through maternal health education, obstetric service for examination and consultation, and nursing service for prenatal delivery and postpartum care In Arizona a mobile tuberculosis unit gives diagnostic and advisory services to referred children

3B Services for Crippled Children (Title V, Part 2) This part of the act is intended to enable each state "to extend and improve, especially in rural areas and in areas suffering from severe economic distress, services for locating crippled children and for providing medical, surgical, corrective and other services and care and facilities for diagnosis, hospitalization and after care for children who are crippled or who are suffering from conditions which lead to crippling" An annual appropriation of \$2,850,000 is provided Again the Children's Bureau dictates policy and controls administration The language of the act is vague, and just what the services mentioned above will consist of depends entirely on the discretion of the bureau Each state having a plan appropriate to the indicated service and approved by the Children's Bureau receives \$20,000 annually, the remaining \$1,830,000 to be distributed "to the states according to the need of each state as determined after taking into consideration the number of

crippled children in such state in need of services' The cost of furnishing such services to the states favored with allotments must be matched by them dollar for dollar A year ago many states had no official agency for providing services to crippled children is a recognized public responsibility There are now such official agencies in forty-six states, up to June, 1936, in twenty-nine of these states the agencies had been approved by the Children's Bureau This section of the act will certainly develop state-wide programs of services to crippled children, although sundry agencies will administer them Co-operation with the vocational rehabilitation services of the state concerned is required

3C Child-Welfare Service (Title V, Part 3)

The act is to enable the United States to co-operate with the states in establishing, extending and strengthening in predominately rural areas child-welfare services for the protection and care of homeless dependent and neglected children in danger of becoming delinquent Ten thousand dollars goes to each state, and \$996,000 is distributed annually among the states No provision is made for the states' obligations to match these sums This part of the act is also directed by the Children's Bureau

5 Vocational Rehabilitation (Title V, Part 4)

This measure authorizes the appropriation of \$1,641,000 for 1936-1937, and thereafter \$1,938,000 annually, to the states in order to extend and strengthen the program of vocational rehabilitation of the physically disabled Each state is to receive, after \$5000 goes to Hawaii, such proportion of this sum as its population bears to the population of the United States, no state to get less than \$10,000, and each state to match this grant, dollar for dollar

6 Public-Health Services (Title VI) This section authorizes an annual federal appropriation of \$8,000,000, to be distributed among the states in order to assist "states, counties, health districts and other political subdivisions of the state in establishing and maintaining adequate public-health services, including the training of personnel for state and local health work This money is distributed on the basis of (1) population, (2) special health needs and (3) financial needs The federal administrative agent is the Surgeon General of the United States Public Health Service and he must approve all plans before any state can receive a grant There is also provision for an annual appropriation of \$2,000,000 to the United States Public Health Service, to be used for 'investigations of diseases and problems of sanitation and for the pay and allowance and traveling expenses of personnel of the Public Health Service

engaged in such investigation or detailed to co-operate with the health authorities of any state"

The success of this general program depends on the wisdom shown in developing well-balanced plans and in securing the co-operation of the many groups interested. At present there is great difficulty in finding persons well qualified to do the work. Thorough training in pediatrics, obstetrics and orthopedics is necessary, as well as a knowledge of public-health problems and procedures. Many recent medical graduates are looking forward to work in the field of public health and are taking postgraduate courses to fit themselves for it. Both the Children's Bureau and the United States Public Health Service are making an earnest endeavor to pick men who will maintain high standards and who have adequate medical background, even though they lack specific public-health training. The Social Security Act has been rushed through with such speed that time will necessarily be needed to train the proper personnel.

A letter of April 6, 1937, from the Children's Bureau, says "To date forty-eight states, Alaska, Hawaii and the District of Columbia have approved plans for maternal and child-health services, forty-two states, Alaska, Hawaii and the District of Columbia have approved plans for services for crippled children, and forty-two states and the District of Columbia have approved plans for child-welfare services." The Public Health Service states in a letter dated April 7, 1937 "All the states, the territories of Alaska and Hawaii and the District of Columbia are participating in the program,"—that is, the grants under the public-health-service section of the Social Security Act.

What part is Massachusetts taking in the functioning of the act? Maternal and child-health service is under the direction and control of the Division of Child Hygiene, and the crippled-children service is directed by the Orthopedic Unit of the Division of Administration, both of which are subdivisions of the State Department of Public Health. The child-welfare program comes under the State Department of Public Welfare.

Our crippled children in Massachusetts have been benefited to the extent of \$85,000 received during the last year. Such a child is defined as "one who is under twenty-one years of age, who is suffering from poliomyelitis, bone or joint tuberculosis, congenital defects (harelip or cardiac disease), arthritis and other similar conditions that may lead to or have produced crippling and that may be treated advantageously." Eleven clinics have been established under the act—in Pittsfield, Greenfield and Springfield in western Massachusetts, in Worcester and Gardner in the central part, in Haverhill,

Lowell and Salem in the northeastern area, and in Fall River, Hyannis and Brockton in the south east. There are no clinics in the Metropolitan area. Each is in charge of an orthopedic surgeon, who gives his services for a nominal fee. The first clinic was opened in Pittsfield September 2, 1936. Through January 15, 1937, thirty-two sessions had been held, 244 children had made 298 visits, 40 had entered hospitals and 750 treatments had been given by the field physiotherapists. The patients must be recommended by their family physicians. Applications are passed upon by a committee from the local district medical society, and when approved, must be finally accepted by the orthopedist in charge of the clinic. This procedure has been approved by the Massachusetts Medical Society. Fortunately these various clinics are in charge of well-known, high-grade orthopedic surgeons.

At Worcester five or six clinic sessions have been held, the patients were all from out of town and almost entirely chronic cases or those requiring free service. I am told by the surgeon-in-charge that this work has proved well worth while. He also states that there has been little or no encroachment on private professional work. Such infringement is an obvious possibility, but with proper control of the clinics this danger is slight. This type of advance by government into medicine has been helpful rather than hampering and has met with general approval and co-operation from lay women, many of whom are giving both time and money. Through the active assistance of the medical profession such governmental activity should prove a mutually beneficial function in socializing the practice of medicine.

The other funds received by Massachusetts under the Social Security Act are used to extend the former health program, with the addition of a number of special projects—the care of premature babies, health surveys, improvement of school lunches, parent education, and research, study and community demonstrations in nutrition and public health nursing. There is some hope that under the public-health section of the act money to extend medical education through clinics and lectures to physicians in various parts of the State will be forthcoming.

What is the future of social security? You have all received a communication from the Committee on Public Relations of the Massachusetts Medical Society, dated February 1, 1937, telling you of approaching legislation on compulsory health insurance in Congress and in our own legislature. Any such legislation is bound to affect all doctors, the issue is one between social science and medical science, the latter is fighting a lone battle, while

social science is backed by many economists, almost all social workers, and the public. Many politicians see in this broad humanitarian issue much chance for patronage and votes.

Are we in for state medicine? It is hard to see any other deduction if compulsory health insurance goes through, for under such a regime the doctor would be under direct control of those who hold the purse strings. Consider the trend of government responsibility in the care of the sick: first it was limited to the insane, next it included those with tuberculosis. Now Massachusetts takes upon itself a large responsibility in dealing with cancer, while New York does the same with pneumonia. Arthritis, cardiac diseases and rheumatism are all engaging considerable public interest. No doctor wants to care for the insane. Terminal cancer cases require so much attention that most Massachusetts doctors are glad to send them to the (politically built) Pondville Hospital, now so crowded that a second one is to be built in the western section of the State. New York has just appropriated \$400,000 to type and furnish free serum for pneumonia, which will help not only the public but the medical profession. Our many veterans' hospitals are an ever present threat that many other diseases may be given government supervision as these hospitals become less occupied by the ex-soldiers.

There is much to be learned from the experience of European countries. As already pointed out, the Workmen's Compensation Act was foisted upon the medical profession, and is only now working more smoothly because there is medical representation on the various administrative boards. Health insurance in England was established without the medical profession's having anything to say, and only recently has it had any worth-while representation on supervisory bodies. It is only fair to add, however, that recently the British Medical Society has asked to have the system extended to those with higher incomes. In Germany and many other countries the doctor has nothing to say about the regulations governing this vital medical problem. It therefore behooves the medical profession to make an exhaustive study of it. We cannot stage a sit-down strike, we must take some action other than mere negative opposition. We cannot fight this movement destructively, but must make counter proposals.

Most leading medical scientists agree with the social scientist that modern medicine is not available to the great majority of the population. It is here that we must co-operate with the social scientists. The latter interpret the problem solely as one of paying out enough money to get the necessary results, while doctors know that many people

continue to prefer patent medicines and employ quacks and cultists, we also know that there is not yet enough first-class medical care to distribute, even were it possible. The profession should realize that this is one of its main weaknesses. Until the medical schools meet this challenge, regimentation by the state will only make matters worse, for before the law competent and incompetent doctors are alike. Improvement in medical education and an increase in professional ability will naturally take a long time, so that we cannot count upon them in our present scheme. We must make some compromise with the social scientist and socialize certain medical services rather than socialize the doctor.

We must stress preventive medicine, that is, we must plan more for health than for better care for the ill. Our health policy must be national in scope, as are policies of defense and education, so that privileged and underprivileged alike will benefit, we must think in terms of the health of the entire population rather than of the illness of one part. The medical problem is only a small phase of the economic problem of low wage-earners, who form 80 per cent of the population, our attack must be on a broader front. Recent studies undertaken so as to discover the inadequacies of our present medical system show that they are more dependent upon poverty, unemployment, intemperance, superstition and inertia than upon a scarcity of doctors, hospitals or free clinics.

In order to carry out such a program we must have leadership from the federal government. If the doctor as well as the social scientist is called into consultation, we can present concrete suggestions dealing with the health of the population as a whole rather than with the illnesses of a relative few.

After thoughtful study of this subject, I wish to make the following recommendations:

1 *Preventive Medicine* We need to emphasize prevention of disease by the marked expansion of public-health services. None of the countries where compulsory insurance is in force can show any reduction in mortality, and many countries, notably Germany and England, show a marked increase. The present venereal-disease program, stimulated by the United States Public Health Service, is a noteworthy attempt to deal early with a disease which may later cause dependency and penury. By socializing such kinds of medical service we can improve the general health.

2 *Local Tax Support for Hospitals* We cannot continue to depend upon private philanthropy to support the hospitals caring for the indigent or low-income group. This cost should be met from local

tax funds, if possible, with state and federal aid under certain conditions and in certain communities. This may mean increasing the courtesy staff at many hospitals, but Class A medical schools now graduate students who must have a hospital connection in order to do their best work, and by selecting the right men we could improve the standard of medicine in our cities. However, if we accept federal aid for our hospitals, we cannot refuse to pay federal taxes to care for maternity cases in Oklahoma or any other state.

3 *Local Tax Support for Laboratories* A great many people go to the hospital to get additional laboratory data and x-ray diagnoses. The personnel and facilities needed to do this work could be put in charge of the Massachusetts Medical Society, thus preventing political corruption, commercialism and favoritism from governing appointments. The establishment of additional laboratories, especially in the rural districts, would give definite help to those living there. They would help the doctor to practice better medicine, reduce hospital care and increase the efficiency of domiciliary service. These stations could be supported by local tax funds or by state or federal grants-in-aid, which might come under the scope of the present Social Security Act.

4 *Local Tax Support for Medical Care of the Indigent and Near-Indigent* Such care should be financed by local taxation so far as possible, with state and federal aid under certain conditions and in certain communities. It has been a tradition in our profession to give poor people adequate medical care, irrespective of their ability to pay. This may be far from "adequate," a word about which we hear so much from the social scientist. "Adequate" care in one case may mean giving bread and milk, in another it may call for the most painstaking, detailed study. Most of the public have no conception of the amount of free care given to the indigent in hospitals, where everyone except the doctor and pupil nurse is paid, in outpatient de-

partments, where many young doctors put in generous parts of their days without any thought of financial reward, and even in doctors' offices and patients' homes. The present Social Security Act, and most other compulsory insurance acts, do not reach this class of people. The help we give them is traditionally unorganized and hit-or-miss, if poor patients were to receive more organized and definite aid much could be done to benefit them.

5 *Establishment of a Federal Co-ordinating Authority* At present some health work is under the guidance of the United States Public Health Service, a branch of the Treasury Department, and some is under the Children's Bureau of the Department of Labor. Instead, it should be centered in a Department of Health, with a medical Secretary of Health, who would be a cabinet officer. We could then attack these problems along broad lines, with good assurance of being able to raise the standard of medical practice and thereby improve public health.

In presenting these plans we must recognize the rapidly changing nature of medical science and avoid any standardization of mediocrity. With federal funds the standards of medical education can be raised and the results of medical research can be made available to many more people. If such steps as I have suggested are not taken by the medical profession itself, we shall find ourselves confronted by a *fait accompli*, having had no voice in the matter and with only ourselves to blame for the result. This is no time for a *laissez faire* attitude. We must overcome our lethargy, educate ourselves as to what should be done, and follow through with united front to bring about such legislation as will be fair to both the practitioner and the public.

21 West Street.

CASE 24051

PRESENTATION OF CASE

A forty-five-year-old Canadian born farmer entered the hospital with the complaint of pain in the right lower quadrant of a month's duration.

He had always been in good health up to a month before entry, when he first had a feeling of "gas" in the lower part of his abdomen. Three weeks before entry he could feel a firm, somewhat tender lump, measuring about 5 cm. in diameter, in his right lower quadrant. He also had dull non-radiating pain in his right lower quadrant which at first was so mild that he forgot about it when he was busy. The pain came on in attacks which occurred daily and lasted from a few minutes to several hours. It bore no relation to urination, defecation or the eating of food, but was relieved by gaseous eructations and the passage of gas by rectum. The attacks of pain became slightly more severe during the two weeks before entry but never caused him very much distress. The tender lump in the right lower quadrant did not increase in size. He did not have bloody or tarry stools, diarrhea, nausea, vomiting, loss of appetite, loss of weight, or any other significant symptoms. During his illness he frequently took milk of magnesia and occasionally other cathartics for relief of the pain. This apparently had the effect of increasing his bowel movements from one to two per day.

His past history and family history were noncontributory.

Physical examination revealed a well-developed, poorly nourished man who was not acutely ill. His trachea appeared to be slightly deviated to the left and there was slight dullness and decreased tactile fremitus without rales at the apex of the left lung. His heart was negative, and his blood pressure was 130 systolic, 90 diastolic. In the right lower quadrant there was a firm, irregular mass measuring about 7 cm. in diameter which appeared to be fixed to the region of the brim of the pelvis. It was tender on its medial aspect. There was no other abdominal tenderness, spasm or rebound tenderness. The liver could be palpated three finger-breadths below the costal margin, and its surface was smooth and non-tender.

The temperature was 98.6°F., the pulse 78. The respirations were 18.

The urine examination was negative. The blood showed a red-cell count of 4,900,000 with 70 per cent hemoglobin. The white-cell count was 8400 with 71 per cent polymorphonuclears. The blood Hinton test was negative.

A barium enema passed freely up to the cecum, where there was a constant filling defect involving the lower part of the cecum. There was a suggestion of slight irregularity of the mucosa of the cecum, and the appearance of this filling defect was that of intussusception. A very small amount of barium passed into the terminal ileum. A gastrointestinal x-ray examination by a motor meal showed a mass measuring about 5 cm. in diameter, involving the pole of the cecum. Overlying the mass there appeared to be transverse mucosal lines in the cecum having the appearance of intussusception. The terminal ileum for about 6 cm. from the ileocecal valve was narrowed and showed normal mucosa and peristalsis with no evidence of intrinsic disease. However, it was displaced upward by the mass in the cecum, and above it the ileum was somewhat dilated. In the region of the mass there was a small area of calcification measuring about 1 cm. in diameter.

On the sixth day a laparotomy was performed.

X-RAY INTERPRETATION

DR. AUBREY O. HAMPTON: We have a barium enema examination and a double contrast enema. Here is the mass that is described. In this picture you can see the defect in the cecum with the transverse folds of mucosa which look like intussusception. In all these pictures there is an area of calcification about the size and shape of the appendix and about 1.5 cm. in length. The calcification is in the center of the mass. The ileum is normal except for displacement. The chest is normal.

DR. ARTHUR W. ALLEN: Did they get the information that his trachea was drawn over to the left from the x-ray or from physical examination? Apparently they thought there was an old apical lesion on the left.

DR. HAMPTON: His trachea is in the midline on the film. He has some indefinite density in the first right interspace, but I do not see anything on the left side.

DR. ALLEN: Does the x-ray department make a definite diagnosis of intussusception in this case?

DR. HAMPTON: The tip of the cecum appears slightly infolded. The condition has not progressed to the point of intussusception of the ileocecal valve, rather just a little pushing in of the cecum, let us say. But even so this could be the beginning of intussusception. I do not know whether one could tell whether the tip of the cecum was pushed up or drawn in.

DR ALLEN Where is the 6 cm of ileum that was narrowed? Can you point that region out?

DR HAMPTON It is not very narrow. There are normal mucosal folds through it. It is displaced rather than actually narrowed.

DR ALLEN Does this represent the hepatic flexure?

DR HAMPTON Yes, very low.

DIFFERENTIAL DIAGNOSIS

DR ALLEN There is so much said about intussusception in this case that we may infer that that is not what he has. The matter with him. But it is a very interesting story which brings up a good many points of interest in differential diagnosis, and I think we must accept the history as it is given.

This man did not come down with any acute illness at the time of onset of discomfort. According to the history his pain was low abdominal pain from the beginning and was that of large-bowel disease. I think there are various possibilities that one might consider. In the first place we start with a palpable tumor in the right lower quadrant. The patient himself discovered this tumor and undoubtedly it excited his curiosity. There was some tenderness in the tumor to palpation, particularly on its medial aspect, but the size of the tumor apparently had not varied much from the time he first noticed it until admission to the hospital. The question of an old apical tuberculosis which has been brought out in the history would make one think of the possibility of tuberculosis in the region of his cecum to account for the filling defect and the tumor. On the other hand I think it would be unlikely for a man to have tuberculosis of the cecum to the point of a palpable mass without having had a longer story of malaise and fatigue and inability to work. His malnutrition may not have been a real one, although it is possible that he had limited his diet somewhat due to resulting discomfort, in spite of the fact that the story says otherwise.

If we are going to consider all the possibilities that might cause a tumefaction with intussusception in the region of the cecum, we of course think of various benign lesions, because most of the intussusceptions of the right side of the bowel are started by benign tumors of some sort, usually not in the lumen of the bowel but in the wall. A lipoma may form in the bowel wall and be the starting point of an intussusception. A lymph-node enlargement in the ileocecal mesentery may start such a lesion. A benign polyp is not an infrequent cause for intussusception in the bowel. And then of course we have the various malignant neoplasms. It is perfectly true that a man may have a consid-

erable lesion in the cecum or ascending colon from which he has no symptoms until it intussuscepts, but when intussusception takes place he is apt to have complete obstruction, he comes in as a case of intestinal obstruction with a palpable tumor on the right side, and not until the intussusception is dislodged by a barium enema or by spontaneous reduction does the relief of temporary obstruction occur, and with this, relief of pain. The fact that this man had had only intermittent pain which was probably cramp-like in character, although it does not say so, means that he was not obstructed. Besides, his bowels moved twice each day with a little milk of magnesia, that, I believe, is the biggest argument against its being intussusception.

If we want to assume that it was not intussusception and argue from that standpoint, what are the causes of masses developing in the right lower quadrant? Of course the commonest cause is appendicitis. The onset of this story is very unlike appendicitis, but we all know that appendicitis may produce any form of abdominal pain and present the widest variations of symptomatology. He had had this difficulty for four weeks, so we may not be too perturbed by the fact that his white count was normal. One might also take into consideration the tenderness of the mass. It does not state whether the skin over it was red. Perhaps it was. It still could be a subacute or very small, low-grade appendix abscess which was well encapsulated and which could be palpated. It might have buried itself into the cecum in such a way as to account for this picture.

The calcification in the center of the mass makes one suspicious of tuberculosis. One can have a low grade tuberculous process in the ileocecal region involving primarily the lymph nodes, in which calcification can take place, and perhaps there could be associated with that a superimposed acute or subacute inflammatory process, which in other nodes might go on to small-abscess formation and still have a calcified node nearby.

I think that this is not cancer, although I am not influenced by the fact that he has so little anemia. Many of the right colon lesions are picked up early enough so that they have not caused anemia. I doubt if it is one of the bizarre diseases like leukemia, amebiasis or actinomycosis. I think it is a benign lesion, not cancer, and the choice lies between tuberculosis and an unusual form of appendix abscess. I should be inclined to say that because of lack of obstruction he did not have intussusception and that his tumefaction was due to some subacute inflammatory process. I should put as my first choice a tuberculous node with calcification and secondary infection of other nodes, and as second choice, some form of appendicitis.

CLINICAL DISCUSSION

DR. RICHARD H. SWEET: I operated on this patient, and we came to exactly the same conclusion before operation that Dr. Allen has reached. We felt that he had an inflammatory process, not a carcinomatous cecum. My preoperative diagnosis was tuberculosis of the cecum. This mass was not tender, but was exceedingly firm and fixed. It felt like carcinoma, but when we opened the abdomen it was obvious that it was a chronic inflammatory lesion. The appendix was not visible except when the ileum was rolled over. It was somewhat adherent in the region of the mass, and one could see about 10 cm. of the dilated tip. The end of the cecum and the appendix region were involved in this inflammatory mass. There were a number, almost a handful, of immensely swollen lymph nodes in the mesentery in that region. It was impossible to free the mass from the underlying peritoneum. We did not know exactly what we were dealing with. We still felt that it was tuberculosis and proceeded with a right colectomy on that basis.

DR. WILLIAM B. BREED: I should like to ask Dr. Hampton if he could say definitely that this small area of increased density is not an area of calcification and that it is not an appendix with barium in it.

DR. HAMPTON: When we first saw the area we thought it was barium, but it remains in all the films and does not have so much density as barium. It does not look like a tuberculous gland. It has the shape of the appendix, and the only thing that you can really attribute it to is a calcified fecalith in the appendix. I saw the film before I knew what happened to the patient and asked the examiner to write in his note that the process was a benign tumor of the appendix, I could not imagine anything else that would produce this picture.

DR. ALLEN: You cannot see this mass in any shape or form similar to a calcified gland?

DR. HAMPTON: No. I am sorry that I did not go into that more before you discussed it. It does not look like any type of calcification that one ordinarily sees.

CLINICAL DIAGNOSIS

Tuberculosis of the cecum

DR. ALLEN'S DIAGNOSES

1. Tuberculosis of the cecum without intussusception
2. Subacute appendix abscess

ANATOMIC DIAGNOSES

Subacute and chronic appendicitis without abscess.
Fecalith

PATHOLOGICAL DISCUSSION

DR. BENJAMIN CASTLEMAN: The specimen that we received consisted of a portion of the ascending colon, the cecum, the appendix and a segment of terminal ileum. The appendix was at first scarcely recognizable since it was somewhat over 2.5 cm. in diameter and was almost buried in the wall of the cecum lying beneath the serosa of the latter. Its gross aspect was therefore most suggestive of a tumor. After a plane of cleavage had been found and it was dissected free, it was evident that the appendix was about 7 cm. in length, its walls averaged a centimeter in thickness and its lumen was patent but contained a fecalith, which was proved to be opaque to x-rays.

Microscopic examination showed no evidence of neoplasm, of tuberculosis or of any specific inflammatory lesion. There was a marked infiltration of all layers of the wall with lymphocytes, plasma cells and a very rare eosinophil. There was some inflammatory edema but most of the thickening appeared to be due to fibroblastic proliferation. The regional lymph nodes, which were numerous and large, showed only an inflammatory hyperplasia.

This is one of the very few appendices we have ever seen in this laboratory which, in the opinion of all the staff, unquestionably warranted the diagnosis of chronic appendicitis. That there was at the time of removal, and had been for at least a month previously, progressive infection and inflammatory reaction seems certain from the microscopic picture. Cases of this sort, however, are far too rare to give any encouragement to the surgeon who still tries to rationalize himself into believing that chronic appendicitis is a justifiable clinical diagnosis.

CASE 24052

PRESENTATION OF CASE

First Admission A thirty-year-old white, male, Irish chauffeur entered the hospital for the first time with the complaint of pain in the left knee of two years' duration.

About two years before entry he noticed the onset of pain in the left knee. It was sharp and knifelike and came on in attacks lasting one or two days. During inclement weather the attacks lasted longer. These attacks gradually became more severe but the pain never spread beyond the knee. About two months before entry he consulted a physician who advised Epsom-salt stupes. These seemed to increase the severity of the pain. One month before entry x-ray studies were made, and an apparent abscess over the upper third of the left tibia was incised and drained. The material obtained was submitted to a patholo-

DR ALLEN Where is the 6 cm of ileum that was narrowed? Can you point that region out?

DR HAMPTON It is not very narrow. There are normal mucosal folds through it. It is displaced rather than actually narrowed.

DR ALLEN Does this represent the hepatic flexure?

DR HAMPTON Yes, very low.

DIFFERENTIAL DIAGNOSIS

DR ALLEN There is so much said about intussusception in this case that we may infer that that is not what he has. The matter with him. But it is a very interesting story which brings up a good many points of interest in differential diagnosis, and I think we must accept the history as it is given.

This man did not come down with any acute illness at the time of onset of discomfort. According to the history his pain was low abdominal pain from the beginning and was that of large-bowel disease. I think there are various possibilities that one might consider. In the first place we start with a palpable tumor in the right lower quadrant. The patient himself discovered this tumor and undoubtedly it excited his curiosity. There was some tenderness in the tumor to palpation, particularly on its medial aspect, but the size of the tumor apparently had not varied much from the time he first noticed it until admission to the hospital. The question of an old apical tuberculosis which has been brought out in the history would make one think of the possibility of tuberculosis in the region of his cecum to account for the filling defect and the tumor. On the other hand I think it would be unlikely for a man to have tuberculosis of the cecum to the point of a palpable mass without having had a longer story of malaise and fatigue and inability to work. His malnutrition may not have been a real one, although it is possible that he had limited his diet somewhat due to resulting discomfort, in spite of the fact that the story says otherwise.

If we are going to consider all the possibilities that might cause a tumefaction with intussusception in the region of the cecum, we of course think of various benign lesions, because most of the intussusceptions of the right side of the bowel are started by benign tumors of some sort, usually not in the lumen of the bowel but in the wall. A lipoma may form in the bowel wall and be the starting point of an intussusception. A lymph-node enlargement in the ileocecal mesentery may start such a lesion. A benign polyp is not an infrequent cause for intussusception in the bowel. And then of course we have the various malignant neoplasms. It is perfectly true that a man may have a consid-

erable lesion in the cecum or ascending colon from which he has no symptoms until it intussuscepts, but when intussusception takes place he is apt to have complete obstruction, he comes in as a case of intestinal obstruction with a palpable tumor on the right side, and not until the intussusception is dislodged by a barium enema or by spontaneous reduction does the relief of temporary obstruction occur, and with this, relief of pain. The fact that this man had had only intermittent pain which was probably cramp-like in character, although it does not say so, means that he was not obstructed. Besides, his bowels moved twice each day with a little milk of magnesia, that, I believe, is the big-
gest argument against its being intussusception.

If we want to assume that it was not intussusception and argue from that standpoint, what are the causes of masses developing in the right lower quadrant? Of course the commonest cause is appendicitis. The onset of this story is very unlike appendicitis, but we all know that appendicitis may produce any form of abdominal pain and present the widest variations of symptomatology. He had had this difficulty for four weeks, so we may not be too perturbed by the fact that his white count was normal. One might also take into consideration the tenderness of the mass. It does not state whether the skin over it was red. Perhaps it was. It still could be a subacute or very small, low grade appendix abscess which was well encapsulated and which could be palpated. It might have buried itself into the cecum in such a way as to account for this picture.

The calcification in the center of the mass makes one suspicious of tuberculosis. One can have a low grade tuberculous process in the ileocecal region involving primarily the lymph nodes, in which calcification can take place, and perhaps there could be associated with that a superimposed acute or subacute inflammatory process, which in other nodes might go on to small-abscess formation and still have a calcified node nearby.

I think that this is not cancer, although I am not influenced by the fact that he has so little anemia. Many of the right-colon lesions are picked up early enough so that they have not caused anemia. I doubt if it is one of the bizarre diseases like leukemia, amebiasis or actinomycosis. I think it is a benign lesion, not cancer, and the choice lies between tuberculosis and an unusual form of appendix abscess. I should be inclined to say that because of lack of obstruction he did not have intussusception and that his tumefaction was due to some subacute inflammatory process. I should put as my first choice a tuberculous node with calcification and secondary infection of other nodes, and as second choice, some form of appendicitis.

osteal elevation along the borders of the shaft X-rays of the chest and long bones were negative
On the sixth day an operation was performed

DIFFERENTIAL DIAGNOSIS

DR. GRANTLEY W. TAYLOR Since this is obviously a bone problem I think we had better look at the X-rays before we start the discussion

DR. GEORGE W. HOLMES In the first film we see a lesion which involves the upper two thirds of the tibia. It apparently stops sharply at the joint surface. There is destruction of the cortex but not complete destruction. It seems to be infiltrated but not completely destroyed, and there is a moderate amount of periosteal reaction. In this film I see no definite soft-tissue tumor. A primary osteogenic tumor of bone with involvement to that extent would certainly be accompanied by soft-tissue tumor. Occasionally a Ewing's tumor, a reticulum-cell sarcoma or some other lymphomatous type of tumor, or, of course, metastatic tumor will present this picture. Even after the process had gone on for a considerable time and had been operated upon there was no involvement of the joint. Osteomyelitis does not always involve the joint, but a lesion with this duration and with this extent of bone involvement should, I think, involve the joint.

In this film you see a considerable soft-tissue shadow which is somewhat lobulated distinctly more so than you would expect in an ordinary case of osteomyelitis. This process is too evenly distributed and the mottling too coarse for osteomyelitis. Furthermore, there is more involvement of the cortex and less of the periosteum than you would expect with chronic osteomyelitis.

DR. TAYLOR Dr. Holmes's remarks are very much more to the point than mine would have been in indicating that this is not a simple case of osteomyelitis. We have positive cultures, we have positive pathological examinations, we have a typical, clinical course, all of which indicate that the diagnosis of osteomyelitis was a logical one to account for at least part of the picture. There are several things that arise in the course of a review of the case which argue that it is not a simple osteomyelitis. First of all there is the fact that this patient began to have symptoms after he was twenty-eight years old and then of a rather mild degree with gradually increasing severity. Such a history is consistent with a Brodie-abscess type of osteomyelitis, which is not at all confirmed by the X-ray studies. This diffuse involvement of the upper end of the shaft is much more consistent with the type of osteomyelitis that sets in in young children before the epiphyses have united.

A similar picture may obtain in the early stages of the infection. His chart and clinical picture at the time of entrance to the hospital did not warrant a diagnosis of osteomyelitis of the sort that is consistent with these X-ray findings. The patient was in fairly good condition, his pulse was not particularly elevated, his temperature was not markedly elevated, he had occasionally increased white counts. So we realize that he must have had an accompanying infection along with his primary lesion, whatever that was. As I have said, he also had a tumor, and the problem is to decide what sort of tumor.

Dr. Holmes has alluded to a few of the tumors which we ought to consider in a case of this sort. Osteogenic sarcoma accounts for the largest proportion of the primary bone tumors. Ewing's tumor is commoner in younger people. The lymphomatous tumors must also be considered. I have not mentioned any benign tumors. There is nothing about this picture which suggests the possibility of benign tumor. Dr. Codman shed light on this case the other day—not discussing this case, however. He said that only one bone may be involved in the early stage of Paget's disease but that the disease does not persist as a one bone disease. If it does, then there is something wrong with the diagnosis. This patient came to the hospital before we routinely did blood-calcium studies and phosphatase determinations, so we do not have these findings to help or confuse the diagnosis.

The problem is, Which of the possible tumors are we dealing with? We have a process with destruction of bone, and a process with the formation of a good deal of new bone. We have something which looks almost like a pathologic fracture and which may have brought about the exacerbation of symptoms that brought him to the hospital. The rather rapid progress of this disease is of interest, namely, at the last admission he looked emaciated, whereas on the first admission two months previously, he was a well-nourished and fairly healthy individual. The progress of the tumor itself is astonishingly rapid so far as the process in the soft tissue is concerned and in the bone. With both Dr. Simmons and Dr. Codman present, I do not feel that I should venture to offer the last word on the diagnosis of bone tumors, but it is my impression that we are dealing with osteogenic sarcoma regardless of the fact that the X-ray picture is not typical. I should say that on the sixth day the tumor was explored for an adequate specimen for the pathological department and that amputation was carried out. I should also say that almost regardless of the nature of the tumor the prognosis was fairly poor.

gist who reported it to show a staphylococcal osteomyelitis. The wound closed in two weeks, but one week later was reopened by the physician, it had drained continuously during the week before entry.

His past history and family history were non-contributory. He denied ever having had venereal disease.

Physical examination revealed a well-developed, fairly well-nourished male in no distress. The physical examination was negative except for the left leg, which showed a discharging sinus about 2.5 cm in length in an operative incision over the upper aspect of the tibia. The area around it was swollen and slightly tender. The knee was held in 30° flexion. Extension and flexion were possible but painful, and there were spasm and atrophy of the thigh muscles.

The temperature was 98°F, the pulse 90. The respirations were 20.

The urine examination was negative. The blood showed a hemoglobin of 70 per cent and a white-cell count varying between 11,000 and 18,000. The blood Hinton was reported negative three times.

An x-ray of the left tibia showed the upper third to have a mottled appearance due to numerous areas of increased density and irregular areas of decreased density. The cortex had a moth-eaten appearance, and there was a considerable amount of new-bone formation about the upper shaft. The changes were quite diffuse, extending from the cartilage surface downward and fading out in the mid-shaft. There was very little increase in the size of the bone. The changes appeared to involve both the medulla and the cortex. An x-ray of the chest was negative.

His chart remained flat, and on the ninth day the lesion was widely incised and packed with iodoform gauze. There was a collection of pus on the anterior surface of the tibia. The bone itself was very dense and stony hard, and the periosteum and superficial cortex were destroyed. Some of the necrotic bone was gouged out. Biopsies were taken which, on pathological examination, showed acute and chronic osteomyelitis. Cultures of the material showed staphylococci in the broth, but no growth on a blood-agar plate. He was discharged on the thirtieth day with his wound still draining.

Second Admission (one week later). During the interval, wet dressings were applied to his wound daily by the district nurse. On the day before re-entry a painful, red, hot swelling appeared just above the wound and increased rapidly in size.

Physical examination revealed the infrapatellar bursa to be red, tender, swollen and fluctuant. There was no lymphangitis or swollen nodes. The operative wound was open and necrotic bone could be seen at its base.

The temperature was 103°F, the pulse 95. The respirations were 28.

The urine examination was negative. The blood showed a white-cell count of 18,500.

On the day of entry the fluctuant area was incised, and a large pocket of pus was found which extended across the entire anterior surface of the tibia just above the upper end of the previous incision. The abscess was packed with iodoform gauze. Culture of the material showed no growth on a blood-agar plate. On the second day the temperature dropped to normal and remained there until discharge. An x-ray on the seventh day showed a large operative defect involving the shaft of the tibia. The amount of bone destruction had apparently increased somewhat. He was discharged on the ninth day.

Final Admission (two months later). For three weeks after discharge he was in good health and thought that his lesion was healing properly. However, at the end of that time, five weeks before re-entry, he began to have very severe pain in his left knee which at first occurred only at night and awakened him from his sleep. Often the pain radiated deep to the inner side of the thigh or down the lower leg to his foot where it was needle-like in character. About two weeks before re-entry the pain had become almost constant, both day and night. At that time he noticed a swelling over the patella which gradually extended around into the popliteal space. It was very hot, red and tender to deep pressure. The swelling around his operative wounds also increased in extent. The wounds had continued to drain pus ever since his last operation. His general health was good except for occasional toothaches. He had no fever or night sweats.

Physical examination showed a somewhat emaciated man. The left knee was very much swollen and held in 30° flexion. There was a large swelling below the left knee with a deep fissure in it, lined by apparent granulation tissue. The skin over the swelling did not seem inflamed. A movable, non-tender node measuring 2.5 by 2 cm was palpable in the left groin.

The temperature was 99°F, the pulse 140. The respirations were 20.

The urine examination was negative. The blood showed a red-cell count of 4,200,000 with 80 per cent hemoglobin and a white-cell count of 14,000 with 64 per cent polymorphonuclears. The blood Hinton was again negative.

An x-ray of the leg showed a large, lobulated, soft-tissue mass surrounding the upper portion of the tibia and the knee joint. The operative defect was less sharply defined and appeared to be partially filled in by new bone. There was some peri-

osteal elevation along the borders of the shaft. X-rays of the chest and long bones were negative.

On the sixth day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. GRANTLEY W. TAYLOR: Since this is obviously a bone problem I think we had better look at the x-rays before we start the discussion.

DR. GEORGE W. HOLMES: In the first film we see a lesion which involves the upper two thirds of the tibia. It apparently stops sharply at the joint surface. There is destruction of the cortex but not complete destruction. It seems to be infiltrated but not completely destroyed, and there is a moderate amount of periosteal reaction. In this film I see no definite soft-tissue tumor. A primary osteogenic tumor of bone with involvement to that extent would certainly be accompanied by soft-tissue tumor. Occasionally a Ewing's tumor, a reticulum-cell sarcoma or some other lymphomatous type of tumor, or, of course, metastatic tumor will present this picture. Even after the process had gone on for a considerable time and had been operated upon there was no involvement of the joint. Osteomyelitis does not always involve the joint, but a lesion with this duration and with this extent of bone involvement should, I think, involve the joint.

In this film you see a considerable soft-tissue shadow which is somewhat lobulated distinctly more so than you would expect in an ordinary case of osteomyelitis. This process is too evenly distributed and the mottling too coarse for osteomyelitis. Furthermore, there is more involvement of the cortex and less of the periosteum than you would expect with chronic osteomyelitis.

DR. TAYLOR: Dr. Holmes's remarks are very much more to the point than mine would have been in indicating that this is not a simple case of osteomyelitis. We have positive cultures, we have positive pathological examinations, we have a typical, clinical course, all of which indicate that the diagnosis of osteomyelitis was a logical one to account for at least part of the picture. There are several things that arise in the course of a review of the case which argue that it is not a simple osteomyelitis. First of all there is the fact that this patient began to have symptoms after he was twenty-eight years old and then of a rather mild degree with gradually increasing severity. Such a history is consistent with a Brodie-abscess type of osteomyelitis, which is not at all confirmed by the x-ray studies. This diffuse involvement of the upper end of the shaft is much more consistent with the type of osteomyelitis that sets in in young children before the epiphyses have united.

A similar picture may obtain in the early stages of the infection. His chart and clinical picture at the time of entrance to the hospital did not warrant a diagnosis of osteomyelitis of the sort that is consistent with these x-ray findings. The patient was in fairly good condition, his pulse was not particularly elevated, his temperature was not markedly elevated, he had occasionally increased white counts. So we realize that he must have had an accompanying infection along with his primary lesion, whatever that was. As I have said he also had a tumor, and the problem is to decide what sort of tumor.

Dr. Holmes has alluded to a few of the tumors which we ought to consider in a case of this sort. Osteogenic sarcoma accounts for the largest proportion of the primary bone tumors. Ewing's tumor is commoner in younger people. The lymphomatous tumors must also be considered. I have not mentioned any benign tumors. There is nothing about this picture which suggests the possibility of benign tumor. Dr. Codman shed light on this case the other day—not discussing this case, however. He said that only one bone may be involved in the early stage of Paget's disease but that the disease does not persist as a one-bone disease. If it does, then there is something wrong with the diagnosis. This patient came to the hospital before we routinely did blood-calcium studies and phosphatase determinations, so we do not have these findings to help or confuse the diagnosis.

The problem is, Which of the possible tumors are we dealing with? We have a process with destruction of bone, and a process with the formation of a good deal of new bone. We have something which looks almost like a pathologic fracture and which may have brought about the exacerbation of symptoms that brought him to the hospital. The rather rapid progress of this disease is of interest, namely, at the last admission he looked emaciated, whereas on the first admission, two months previously, he was a well-nourished and fairly healthy individual. The progress of the tumor itself is astonishingly rapid so far as the process in the soft tissue is concerned and in the bone. With both Dr. Simmons and Dr. Codman present, I do not feel that I should venture to offer the last word on the diagnosis of bone tumors, but it is my impression that we are dealing with osteogenic sarcoma regardless of the fact that the x-ray picture is not typical. I should say that on the sixth day the tumor was explored for an adequate specimen for the pathological department and that amputation was carried out. I should also say that almost regardless of the nature of the tumor the prognosis was fairly poor.

DEPARTMENT OF MENTAL DISEASES

DURING the past year a Recess Commission, appointed by Governor Hurley, has been examining the state mental hospitals with a view to ascertaining the merits and demerits of the system and of making such recommendations to the Governor and Legislature as would tend to improve the care of the patients and in general increase the efficiency of the hospitals in carrying out the purposes for which they were established. This commission appointed committees from the personnel of the state institutions and other psychiatrists of prominence to make reports to it on a variety of subjects connected with the various phases of hospital administration and care. These subcommittees reported to the commission and recently this body made a lengthy report to the Governor in which were incorporated its recommendations.

It is gratifying to note that the commission found that, on the whole, the administration of the state hospitals of Massachusetts was efficient and humane, and thus lived up to the traditional standard of this Commonwealth. Despite the recent cataclysm which removed from the service of Massachusetts several distinguished psychiatrists, they found that the morale of the institutions was good, research was going on in several places in a creditable manner, the patients were on the whole well cared for, and the superintendents and personnel of the institutions were men and women of standing. There were minor criticisms, these related generally to the executive work of the institutions.

The most important recommendation which the commission made was in regard to the central executive division in the Department of Mental Diseases. At present there is a paid commissioner and four unpaid associates. In addition to the unpaid commissioners there is one assistant commissioner and three assistants to the assistant commissioner who are men selected from the state hospital service and who are, so to speak, being groomed for superintendencies and other executive positions in the state service. This training is an important and valuable part of the set-up. It is proposed that three commissioners be appointed who are to be paid. The first executive would be a psychiatrist of at least seven years' experience and one who is a member of the American Board of Psychiatry and Neurology. Of the other two, one would be a physician, not necessarily a psychiatrist, and the other a person with civic and executive experience. This group of three would supplant the present unitary head and in general take over the powers of the boards of trustees of the various institutions, including the appointments of the entire medical personnel, the duties of the boards would be minor and supervisory rather than as at present collateral with the powers of the superintendents of the various institutions.

There are several things to be said in favor of and against the proposed changes. From the standpoint of efficiency it would seem better theoretically to have the superintendents appointed by the commissioners rather than by the boards of

DR TRACY B MALLORY Have you any comment, Dr Codman?

DR ERNEST A CODMAN I did not come in in time to hear the story. The films suggest that the lesion is such a difficult one to diagnose that I should like to avoid any trouble. Do not believe what Dr Taylor says. When he can diagnose a case, I probably can, and vice versa. But when we are both puzzled, the x-ray man will probably be puzzled and the pathologist also.

DR MALLORY Every bone-tumor patient in this hospital is an old friend of Dr Simmons. He can tell us more about this patient than anyone else can.

DR CHANNING C SIMMONS I know this case because I operated on the patient. I did not see him until the third admission, when he had a fungating ulcerating tumor, visible in the third x-ray film. We reviewed the x-rays, and Dr Holmes changed his diagnosis, based on the earlier films, to tumor and osteomyelitis. In talking with Dr Mallory, he was not sure the sections were merely osteomyelitis and thought there might be tumor as well. Therefore we amputated, and discovered it was a reticulum-cell sarcoma. The man is perfectly well, three and a half years later. It is one of those unusual tumors of the reticulum-cell type, which metastasize very late. Unquestionably it is failure to recognize this type of tumor which accounts for many of the so-called cures of osteogenic sarcoma.

PREOPERATIVE DIAGNOSIS

Ewing's tumor

DR TAYLOR'S DIAGNOSES

Osteogenic sarcoma
Osteomyelitis (secondary)

ANATOMIC DIAGNOSIS

Reticulum-cell sarcoma

PATHOLOGICAL DISCUSSION

DR MALLORY This is a type of tumor that Dr Frederic Parker, Jr., at the Boston City Hospital deserves the credit for recognizing and describing. He has pointed out that it is a fairly common primary tumor of the bone, and as Dr Simmons has said, the prognosis is relatively good compared with that of any other primary malignant tumor of bone. At the time when this case was biopsied and operated upon I was not recognizing this tumor, and I called it a Ewing tumor. It was not osteogenic sarcoma, nor did it look like lymphoma, I did not know what to call it. It was definitely not characteristic of Ewing's tumor, but for lack of anything better, that is what we put down. In reviewing the slides in subsequent years, it has become clear to all of us, and Dr Parker has checked on the specimen, that it is a rather typical example of reticulum-cell sarcoma. There was, however, very extensive secondary inflammation, and the first biopsy was quite an unsatisfactory one. On a specimen similar to that removed at the second biopsy we should be able today to make a correct diagnosis.

disease is cured by a few tablets which can be purchased at any drugstore, not only will the respect for gonorrhea diminish, but many people will consider themselves cured when actually they are highly infectious. In the last paragraph of the article, reference is made to the serious complications that may result from sulfanilamide treatment, we fear that some readers may not read that far, or if they do, may disregard the warning.

Such publicity as this is misleading and dangerous, and may be the means of damning a really useful drug.

CASE HISTORY No 57 PREMATURE SEPARATION OF THE PLACENTA

Mrs H, a white, thirty-three-year-old woman in her second pregnancy, was eight months pregnant when admitted to the hospital at 10.30 a. m., December 3, 1934. She complained of abdominal pain, dizziness, blurred vision and vaginal bleeding of two and a half hours' duration. This pregnancy had been uneventful until November 23, when she experienced some lower abdominal pain, which disappeared in a few hours. Her ankles had begun to swell on November 29. Slight vaginal bleeding had occurred December 1, but there was no associated abdominal pain. The family physician had found a high unengaged fetal head, the edema of the ankles had increased and the hands had become puffy. Her physician was called on the morning of entry and noted marked bleeding from the vagina and a uterus of board-like consistence. At this time abdominal pain and uterine tenderness were marked and persistent. She had not experienced fetal motion since 6.00 a. m.

There was no family history of diabetes, tuberculosis, cardiorenal disease or malignancy. The patient's health had always been good. Her periods began at fourteen and had always been regular and of the twenty-eight-day cycle. She had had an uncomplicated pregnancy in 1920. Her last period

started on March 24, making the expected date of confinement December 31.

On physical examination there was a generalized edema. The mucous membranes were pale. Her tongue was coated and pale. The lungs were normal. The heart was not enlarged, and there were no murmurs. Her blood pressure was 144 systolic, 110 diastolic, the pulse was 80 and exceedingly weak. The uterus was the size of a full-term intrauterine pregnancy and was of ligneous consistence, it was impossible to outline definitely the fetus. The fetal heart was not audible. Palpation of the uterus caused excruciating pain.

A catheter specimen of urine revealed a large trace of albumin and many finely granular and hyaline casts. Blood examination showed a count of 2,800,000 red blood cells, with a hemoglobin of 58 per cent (Sahli). Blood typing and matching for transfusion were immediately carried out, and the patient was prepared for vaginal examination.

She was transferred to the operating room which was set up for a laparotomy as well as for pelvic examination. She was anesthetized with light gas-oxygen anesthesia. A sterile vaginal examination revealed that the head was high, but it could be pushed into the pelvis, a fact which showed there was no cephalopelvic disproportion. The cervix was soft and measured 1 cm. in thickness, the internal os was 1.5 cm. in diameter. There was no evidence of placenta previa. The fetal membranes were artificially ruptured, and as much amniotic fluid as possible was drained from the uterus. The amniotic fluid was clear. The lower uterine segment, cervix and vagina were tightly packed with nine yards of sterile 2-inch gauze. Thick perineal pads were applied to the vulva. Two many-tailed abdominal binders were tightly applied to the abdomen from above downward. A perineal binder was tightly applied over the perineal pads and fastened securely to the abdominal binder. A special sheet, 45 cm. wide, was then applied around the patient's abdomen at the level of the uterus and tightened from the side (Spanish windlass). Morphine sulfate ($\frac{1}{4}$ gr.) was administered in the operating room.

The patient was returned to the labor room in fairly good condition at 12.30 p. m. The blood pressure was 135 systolic, pulse 88. At 1.00 p. m. she was given 0.13 cc. (2 min.) Pitocin intramuscularly, this was repeated every forty-five minutes for three doses. She was then given 0.2 cc. (3 min.) every forty-five minutes for three doses. Labor began at 1.30 p. m. and progressed normally. Morphine sulfate ($\frac{1}{6}$ gr.) was given at 1.30 p. m. Sodium amytal (6 gr.) was administered by rectum at 2.00 p. m. Throughout the labor the blood pressure remained between 135 and 142 systolic,

trustees, since laymen are presumably not sufficiently well acquainted with the qualifications of a psychiatrist to make a selection for such an important office. There is, however, a serious danger in overcentralization of power, one which should be carefully weighed against the factor of efficiency. It is conceivable that a governor might, by obtaining ascendancy over the commissioners, make a clean sweep of every physician in the state-hospital service. Such abuse of power is not without precedent, even in Massachusetts. On the whole, there ought to be a factor of safety—a buffering power, so to speak—against the possibility of political interference. It has been quite common in several of the western states for a new governor to remove through the commissioner's office the superintendents of the state hospitals and many of the important officers so that no continuity in service and experience was possible. While the power of the trustees should be modified, there ought to be provision made so that they can exert the effect of a brake against any drastic moves initiated in the commissioners' office.

Insofar as the change from one commissioner to three is concerned, the advantage to be gained does not seem to be clear. If a board of three is to be appointed, it would seem advisable to have, in addition to a psychiatrist as the first executive, an engineer, who would look after all the construction and physical maintenance problems of the institutions, and a steward, who would supervise the housekeeping, as the other two commissioners. There is no reason to expect that a psychiatrist will be a good engineer and a good steward in addition to his capability of controlling the medical care of the twenty odd thousand institutional patients.

It would seem better to have a single commissioner—a psychiatrist of at least ten years' experience and a member of the American Board of Psychiatry and Neurology, whose previous career has shown executive ability. On his staff of assistant commissioners there should be a chief engineer and a chief steward, as well as the present group of younger psychiatrists who are being trained for the higher executive positions.

All in all, the Recess Commission is to be congratulated on its fidelity to the job which it undertook, and medical men may well feel that all is not lost in the state hospitals of Massachusetts and that a tradition of service and humanitarianism, pre eminent in the country, is still being maintained irrespective of political eruptions and personal catastrophes.

SULFANILAMIDE AND GONORRHEA

PHYSICIANS who read *Science News Letter* for December 18, 1937, must have been astounded at the double column heading on page 388 proclaiming "Gonorrhea Cured in Three Days by Sulfanilamide Treatment." The first paragraph reports Professor Alyea of Duke University as saying that of one hundred and fifty-eight patients so treated, four fifths "made these rapid recoveries."

Without having Professor Alyea's article for study, one is not in a position to criticize this statement. It may be said, however, that results even approximating these have not been obtained in this section of the country. Sulfanilamide gives promise of being a most useful drug in the treatment of gonorrhea, it is perhaps the nearest approach that we have to a specific remedy. Its use, even in relatively small doses (30 or 40 grains a day), will cause a cessation of discharge within a few days, but the absence of appreciable discharge does not necessarily mean that the infection has cleared up. Even at that time, gonococci in large numbers may be found in the mucoid secretion of the urethra, and after the discontinuance of sulfanilamide, purulent urethritis may develop again. We must acquire a much greater experience in the use of this drug before we can speak with certainty of its value in the management of gonococcal infections.

It is most unfortunate that results such as these quoted by *Science News Letter* are presented to the lay reader. For years social hygiene organizations have endeavored to build up in the public consciousness an appreciation of the serious nature of gonorrhea and of the necessity for adequate medical treatment until the infection is thoroughly eradicated. If the public is led to believe that the

CONNECTICUT NEWS

HARTFORD HOSPITAL TO ENLARGE

The Hartford Hospital plans to break ground this spring for its new power plant, the first step in a \$2,500,000 construction program. Many gifts to this fund have been received recently, the largest single one being \$100,000 from Mrs Era C. Root, widow of Dr Edward K. Root for forty years a member of the Hartford Hospital staff Mrs. Root gave another \$100,000 to be held by the hospital as the Edward King Root Maintenance Fund, the income to be used for current purposes of the institution

The nursing department of the hospital has become new hospital conscious and as a result has presented \$400 to the executive committee. Included in this contributing group were the graduate nurse staff, student nurses, training school-office staff, ward helpers, orderlies, sewing and dressmaking departments, surgical supply department, waitresses, kitchen staff, and chambermaids and telephone operators in the nurses' residence. The superintendent of nurses expressed the hope that the gift would inspire other employees of the hospital, as well as the public, to do their share.

CONTROVERSY OVER HARTFORD MUNICIPAL HOSPITAL

Mayor Spellacy, in his message to the Board of Aldermen on December 13, proposed that the Municipal Hospital be converted into an isolation hospital and that Hartford's indigent be hospitalized in the city's three privately endowed hospitals. Thus, the mayor stated, would save the city at least \$150,000 Careful study of the problem has revealed that such a step would actually cost the city more money It is a very real question whether the three private hospitals, as they stand today, could care for the indigent sick of the city The Mayor has set everyone thinking, and the result will probably be further economies in the management of the Municipal Hospital.

PROTECTION AGAINST HAZARD OF SPRAY COATING

The application of lacquer by means of a spray gun is an important industrial operation. The material sprayed contains some pigments which are toxic and from 75 to 90 per cent by weight of solvents, diluents and thinners, all of which are toxic, some much more so than others. It has been found increasingly evident that this spraying process is not properly safeguarded, particularly when the work is intermittent as in garage and auto-repair shops.

PUERPERAL MORTALITY DROPS

The deaths in Connecticut from puerperal diseases during the first ten months of 1937 were 57 as compared with 92 in the corresponding period of 1936 This decrease of 35 is most significant.

DEDICATION AT TRINITY COLLEGE

In Trinity College Chapel on December 11 a carved pew end was unveiled as a tribute to Horace Wells, discoverer

of anesthesia The ceremonies were a feature of a special vesper service attended by members of the Horace Wells Club, the Hartford Medical and Dental societies and students of Trinity College. The date marked the anniversary of the day in 1844 on which Dr Wells had Professor Colton, an itinerant lecturer on chemistry, administer nitrous oxide or laughing gas to him while he submitted to a dental operation at the hands of his friend Dr Riggs An address, outlining the scientific and historical aspects of the discovery of anesthesia, was made by Dr Walter R. Steiner, librarian of the Hartford Medical Society Library

The pew end contains three carved figures, a profile of Dr Wells in the center, a figure of Aesculapius, Greek god of medicine, at the top, and a representation of St. Apollonia, aged martyr at Alexandria and patroness against toothache

ANNUAL MEETING OF HARTFORD MEDICAL SOCIETY

The Hartford Medical Society held its annual meeting on January 3 Dr Edward J Whalen succeeded Dr Otto G Wiedman as president. Dr Howard W Brayton was elected vice president, and Dr J Raymond Glazier, secretary. Dr Franklin L. Lawton was re-elected treasurer, and Dr Walter R. Steiner, librarian. Dr Wiedman was presented with an engraved gavel on behalf of the members of the society by Dr Brannard In his address the retiring president discussed the increasing frequency of psychoneuroses as a cause of economic loss

TUFTS COLLEGE MEDICAL SCHOOL ALUMNI

The alumni of Tufts College Medical School in Hartford County met in Hartford on January 10 Dr Sidney H. McPherson presided. Drs Louis E Phaneuf, Alonzo K. Paine, Charles A. Haney, and Dean A. Warren Stearns were guest speakers Teams were organized to aid in raising \$2,000,000 for a new medical building and endowment fund at Tufts

CONNECTICUT DELEGATES AT WASHINGTON

Eight delegates attended the conference at Washington on better care for mothers and babies This conference was called by the Children's Bureau and arranged through a planning committee including every organization from the American College of Surgeons to the Junior League. The Connecticut delegates were Dr Stanley H. Osborn, commissioner, State Department of Health. Dr Martha L. Clifford, director, Bureau of Child Hygiene, Miss Hazel V. Dudley, R.N., director, Bureau of Public Health Nursing, Dr Ira V. Hiseock, professor of public health, Yale University. Dr Joseph I. Linde, Connecticut chairman, American Academy of Pediatrics, Dr J. Harold Root, president, Hezekiah Beardsley Pediatric Club, and Dr Robert M. Lewis, of New Haven.

HEALTH OFFICERS APPOINTED

Arthur J. Couture, M.D., has been appointed town health officer of Sterling for a term of four years.

George S. Lambert, M.D., has been appointed health officer for the borough of Danielson and acting health officer for the town of Killingly

DEATHS

TENNEN—JOSEPH S. TENNEN, M.D., forty three, physician in Stamford for twelve years, died in the University of Michigan Hospital, Ann Arbor, Michigan, December 12,

pulse between 88 and 96. The cervix was fully dilated at 4 30 p. m. The pack was expelled at 5 00 p. m. and was followed by a stillborn infant weighing 5 lb., 12 oz. Upon delivery of the infant the placenta was immediately expelled, followed by 1200 cc of blood with clots. The uterus continued to ooze slightly, but this was controlled by uterine tamponade. The blood pressure after delivery remained low. Because of the large blood loss, a transfusion of 500 cc of citrated blood was given. The blood pressure then rose from 75 systolic to 130 systolic, 80 diastolic, and the pulse came down from 130 to 104. The uterus reacted well, and there was no staining through the pack. This was removed twenty-four hours later, following which the uterine flow was normal.

On December 6, three days after delivery, there were 2,500,000 red-blood cells per cu. mm., and the hemoglobin was 48 per cent. Urine examination showed a very slight trace of albumin and an occasional cast. On December 13 the phenolsulfonphthalein test showed 34 per cent excretion of the dye in two hours. Two days later the Mosenthal test revealed a variation of specific gravity during the day of from 1.010 to 1.013. The non-protein nitrogen was 52 mg. per cent, and the blood pressure 140 systolic, 108 diastolic. On December 17 the hemoglobin was 74 per cent, red-blood-cell count 3,900,000—an improvement following iron plus dietary treatment. The urine showed the slightest possible trace of albumin and no casts.

She was discharged on the fourteenth postpartum day after having made an afebrile, uncomplicated convalescence except for slight subinvolution of the uterus.

Comment. This case illustrates the value of the conservative treatment of rupturing the membranes, packing the cervix and vagina, and applying a many-tailed bandage for fundal pressure, in the presence of a dead baby and placental separation. There is always the remote possibility that the uterus cannot contract after delivery, which may necessitate hysterectomy. While this is possible, it is not probable, and its frequency does not make the abdominal operation justifiable.

The use of small doses of Pitocin, or other drugs containing extracts of the posterior lobe of the pituitary gland, in cases that are being induced, has a distinct place in obstetrics. Its use should be limited to the hands of men who are trained in obstetrics. The size and frequency of the doses used in this case are open to criticism. Most men would use only 0.07 cc (1 minim) and repeat only once.

MEDICAL POSTGRADUATE EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau, have been arranged for the week beginning February 7.

BRISTOL NORTH

Thursday, February 10, at 4 00 p. m., at the Morton Hospital, Taunton. Subject: Differential Diagnosis of Scarlet Fever and Its Treatment. Instructor: Edwin H. Place. Arthur R. Crandell, *Chairman*.

BRISTOL SOUTH (New Bedford Section)

Friday, February 11, at 4 00 p. m., at St. Luke's Hospital, New Bedford. Subject: Prophylactic Measures in the Treatment of Measles. Instructor: R. Cannon Eley. Robert H. Goodwin and Howard P. Sawyer, *Chairmen*.

ESSEX SOUTH

Tuesday, February 8, at 4 00 p. m., in the Nurses Home, Salem Hospital, Salem. Subject: Recent Advances in the Diagnosis and Treatment of Heart Disease. Instructor: Sylvester McGinn. Walter G. Phippen, *Chairman*.

MIDDLESEX EAST

Tuesday, February 8, at 4 00 p. m., at the Melrose Hospital, Melrose. Subject: The Use of Vitamins in Pediatric Practice. Instructor: Louis K. Diamond. Joseph H. Fay, *Chairman*.

MIDDLESEX NORTH

Friday, February 11, at 7 00 p. m., at St. John's Hospital, Lowell. Subject: Treatment of Burns. Instructor: Robert H. Aldrich. William S. Lawler, *Chairman*.

NORFOLK

Friday, February 11, at 8 30 p. m., at the Norwood Hospital, Norwood. Subject: Bleeding in the First Trimester of Pregnancy. Instructor: Raymond S. Titus. Hugo B. C. Riemer, *Chairman*.

NORFOLK SOUTH

Monday, February 7, at 8 30 p. m., at the Quincy City Hospital, Quincy. Subject: Complications in Obstetrics Illustrated by Case Histories. Instructor: Roy J. Heffernan. David L. Belding, *Chairman*.

PLYMOUTH

Tuesday, February 8, at 4 00 p. m., in the Rosa Field Nurses Residence, Brockton Hospital (rear of hospital), Brockton. Subject: Pneumococcus Pneumonia and Serum Therapy. Instructor: Frederick T. Lord. Walter H. Pulsifer, *Chairman*.

WORCESTER (Milford Section)

Thursday, February 10, at 8 30 p. m., in the Nurses Home of the Milford Hospital, Milford. Subject: The Use of Vitamins in Pediatric Practice. Instructor: Harold L. Higgins. Joseph Ashkins, *Chairman*.

Serum for Type VIII is in preparation and as soon as it is available, it can be obtained in the same laboratories as Types II, V and VII.

†Therapeutic serum is not available through this laboratory.

*No typing done at this laboratory.

Additions to and changes in this list are made from time to time. Due to the high cost of the serum the number of distributing stations is kept as low as possible. At present Type I serum is easily available in all parts of the State and serums for certain higher types are available at strategic points. The distribution of pneumococcus-antibody solutions is restricted to those hospitals, institutions or agencies equipped to do pneumococcus typing and employing bacteriologists or laboratory technicians who have been approved by the Department of Public Health as to their familiarity with typing procedures.

CORRECTION

In the January 27 issue of the *Journal* appeared a notice of the death of Dr. William Paris, of 139 Washington Avenue, Chelsea. Dr. Paris is very much alive, and the staff takes this opportunity of offering its apology for whatever inconvenience has resulted from the error.

RECENT DEATH

RESTALL—MALCOLM MORRIS RESTALL, M.D., of 66 Pleasant Street, Marblehead, died suddenly January 25 at his home. He was in his fortieth year.

Born in Everett he received his early education there, later attending Roxbury Latin School and graduating from Harvard University in 1922. He received his degree from the Harvard Medical School in 1926. After serving his internship at the Albany Hospital, Albany, New York, Dr. Restall established a practice in Marblehead. He was a staff member of the Salem Hospital and was also associated with the Mary Alley Hospital in Marblehead.

Dr. Restall was a fellow of the Massachusetts Medical Society and of the American Medical Association.

His widow, a daughter, his parents and a sister survive him.

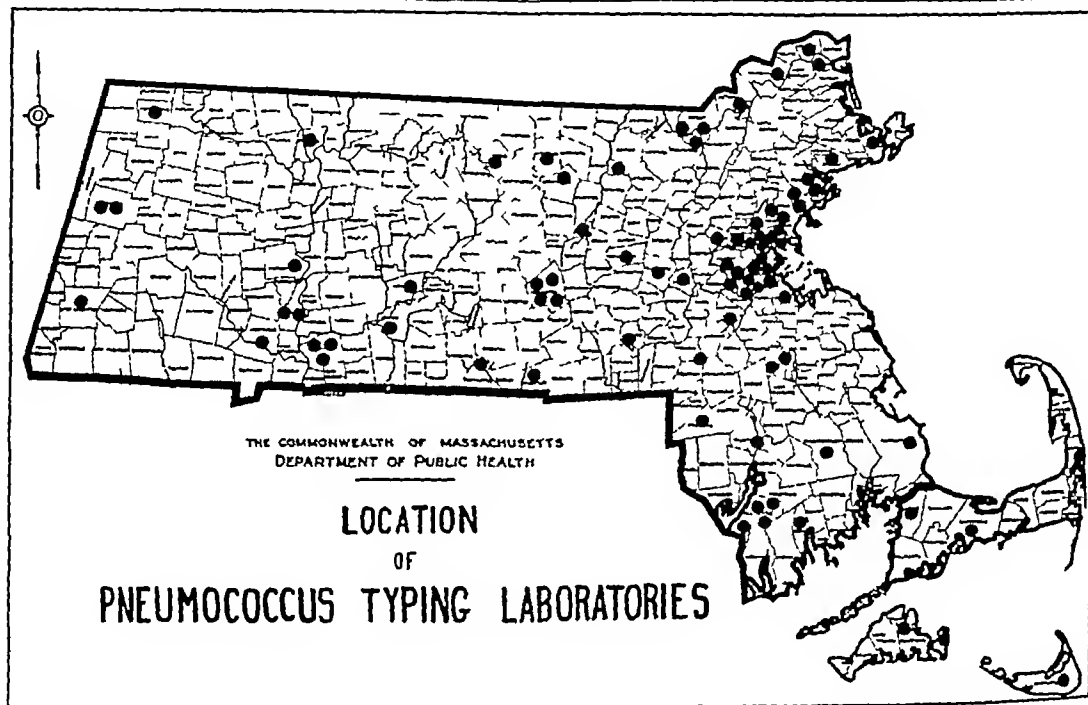

after an illness of three weeks. He is survived by his widow, daughter, father and mother.

BOYCE—**ROBERT V. BOYCE, M.D.**, forty-seven, former president of the Hartford Board of Health and a physician in the public schools, died of pneumonia at St. Francis Hospital on December 29. A native of Hartford, Dr. Boyce was a graduate of the University of Vermont College of Medicine and began general practice in Hartford following the World War. He was an obstetrician on the staff of St. Francis Hospital at the time of his death.

Dr. Boyce was vice president of the first Hartford Board of Public Welfare, formed after the old Board of Charities was abolished. He was appointed to the health board in 1933 and in 1936 was unanimously elected its head. During the flood of March, 1936, Dr. Boyce, as president of the board, worked tirelessly to direct the city's precautionary measures to prevent spread of disease as a result

of flood conditions. Under his direction inoculation of thousands of children and adults against typhoid fever was accomplished. In May, 1936, Dr. Boyce was named acting health officer of Hartford and in July of the same year resigned from the board at the expiration of his term as acting health officer. At the suggestion of Dr. Boyce the Division of Tuberculosis was added to the Hartford Board of Health in 1935, operating under the direction of a part time physician. Dr. Boyce was a member of the Hartford, Hartford County and Connecticut State medical societies and the American Medical Association.

He was the son of the late Mr. and Mrs. Robert H. Boyce. His wife, the late Mary (Murray) Boyce, died in June, 1935. He leaves four children: William M. Boyce, a student at Connecticut State College, Mary Elizabeth Boyce, Helen Burchmans Boyce, and Robert V. Boyce, Jr. He also leaves a sister, Mrs. David Broderick, of Oak Park, Illinois.

CORRESPONDENCE

PNEUMOCOCCUS-TYPING AND SERUM DISTRIBUTION SERVICE

To the Editor—The Massachusetts Department of Public Health is glad to be able to announce that anti-pneumococcal serum for Type VII is now available throughout the State. Serum for Type V has been available since late in the spring, so that pneumonias caused by Types I, II, V and VII can now be treated with serum available from this department. Serum for Type VIII is in preparation, and it is hoped that a supply will be released in the near future.

The present plan is to have a monovalent Type I serum, a bivalent serum for treating cases due to Types II and V, and a bivalent serum for treating cases due to Types VII and VIII. During the next few months a certain amount of the serum available will be bivalent serum for treating Types I and II, but as soon as present

supplies of this are exhausted, Type I will always be a monovalent serum.

Type I serum will be available at most of the approved typing laboratories throughout the State, as can be noted from the accompanying list. The supplies of the higher type serums are not sufficient to warrant placing them in all these laboratories, consequently they will be found at a few strategically located points throughout the State, as noted on the accompanying list. When serum for Type VIII is available, it can be obtained from the latter stations.

The dosage recommended for uncomplicated cases of Type VII is from 60,000 to 90,000 units, this should be increased under conditions outlined in the circular which accompanies the serum. When Type VIII is available, the dosage recommended for uncomplicated cases is 100,000 units.

HENRY D. CHADWICK, M.D.,
Commissioner of Public Health

State House,
Boston

BOSTON UNIVERSITY MEDICAL SOCIETY

There will be a meeting of the Boston University Medical Society in the Evans Memorial Auditorium, 78 East Concord Street, Boston, on Monday evening, February 7, at 8 o'clock.

PROGRAM

Presentation of Case.

Observations on the Diagnosis and Treatment of Brain Tumors. Dr Gilbert Horrax.

Medical students, nurses and physicians are cordially invited to attend.

BOSTON CITY HOSPITAL

The monthly clinicopathological conference will be held at the hospital on Wednesday, February 9, at 12 o'clock noon, in the Pathological Amphitheater

JOSEPH E. HALLISEY, M.D., *Secretary*
Medical Staff

GEORGE WASHINGTON GAY LECTURE

The annual George Washington Gay lecture at Tufts College Medical School will be delivered by Dr R. Nelson Hatt, of Springfield, on Thursday, March 3, at 4 00 p m.

Physicians, students and others interested will be welcome.

DWIGHT O HARA, M.D., *Vice Dean*

CUTTER LECTURE ON PREVENTIVE MEDICINE

The Cutter Lecture on Preventive Medicine will be given at the Harvard Medical School Amphitheater Building E, on Tuesday, February 15, at 5 00 p m. Dr Andrija Stampar, a member of the secretariat of the League of Nations, a delegate of the League of Nations to the National Economic Council of China, former director of health of Yugoslavia and professor extraordinarius for social hygiene in Zagreb, Yugoslavia, will speak on "Observations of a Rural Health Worker"

BOSTON DISPENSARY

25 Bennet Street, Boston
Lecture Hall, Second Floor, 9-10 a. m.

MEDICAL CONFERENCE PROGRAM, FEBRUARY, 1938

Friday, February 4—Present Status of Sulfanilamide Therapy Dr Maurice A. Schnitzer

Saturday, February 5—Recollections of Osler and MacKenzie. Dr Joseph H. Pratt

Tuesday, February 8—Follow up of Interesting Diagnostic Problems Presentation of former patients in the Diagnostic Hospital. Dr Heinrich G. Brugsch.

Wednesday, February 9—Hospital Case Presentation. Dr S J Thannhauser

Thursday, February 10—Social Service Case Presentation. Mrs. H. B. Hooker and Miss E. Grundy

Friday, February 11—Emotional Factors in Asthma Dr Felix Deutsch.

Saturday, February 12—Hospital Case Presentation. Dr S J Thannhauser

Tuesday, February 15—Clinicopathological Conference. Dr R. C. Wadsworth.

Wednesday, February 16—Hospital Case Presentation Dr S J Thannhauser

Thursday, February 17—Hyperventilation Syndromes Dr Maurice Sokolow

Friday, February 18—Some Recent Developments in Purpura and Hemophilia Dr Frederick J. Pohle

Saturday, February 19—Hospital Case Presentation. Dr S J Thannhauser

Wednesday, February 23—Hospital Case Presentation. Dr S J Thannhauser

Thursday, February 24—Gastrointestinal Clinic. Dr K S Andrews.

Friday, February 25—The Diagnosis of Multiple Myeloma. Dr Bernard Jacobson.

Saturday, February 26—Hospital Case Presentation. Dr S J Thannhauser

ALUMNI DAY—NEW YORK UNIVERSITY COLLEGE OF MEDICINE

All graduates of the New York University College of Medicine are cordially invited to participate in Alumni Day activities at the Medical College on Tuesday, February 22. As a fitting tribute to Dr John Wyckoff, the Committee on Science and Education has arranged a comprehensive and attractive program on heart disease. There will be special exhibits and demonstrations to illustrate the papers presented.

A complimentary luncheon will be given by the Alumni Association in the Student Lounge, and the last official function will be an informal reception at which Dean Currier McEwen will be the host. Since many classes have arranged for reunions that evening, the annual association dinner has been cancelled.

MASSACHUSETTS PSYCHIATRIC SOCIETY

The Massachusetts Psychiatric Society will hold its next meeting at the Boston Psychopathic Hospital on Friday evening, February 25, at 8 o'clock. Dr Ives Hendrick will speak on "The Contributions of Psychoanalysis to Psychiatry"

W FRANKLIN WOOD, M.D., *Secretary*

SOUTH END MEDICAL CLUB

The next regular meeting of the South End Medical Club will be held at the headquarters of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston, on Tuesday, February 15, at 12 noon

Dr Dameshek will speak on "Hematological Problems in General Practice."

All physicians are cordially invited to attend.

JOHN B HALL, M.D., *Secretary*

HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held in the Peter Bent Brigham Hospital amphitheater (Shattuck Street entrance), Tuesday, February 8, at 8 15 p m.

PROGRAM

Presentation of Cases

The Aging of Some Homeostatic Mechanisms. Dr Walter B. Cannon.

Medical students and physicians are cordially invited to attend.

MARSHALL N FULTON, M.D., *Secretary*

REPORTS OF MEETINGS

HARVARD MEDICAL SOCIETY

A meeting of the Harvard Medical Society was held at the Peter Bent Brigham Hospital on December 7, Dr. John Homans presiding.

The first case was presented from the medical service by Dr. Reifstein. The patient was a 41 year-old clothing cutter. His past history was uneventful until somewhat over 2 years before entry when, while exercising strenuously, he had a sudden attack consisting of a sensation of severe pressure under the midsternum. This sensation radiated to the shoulders, and down the arms as far as the elbows. It was accompanied by nausea, perspiration and a sense of malaise. He had been promptly treated with bed rest, morphine and nitroglycerin, and after a few days had been able to resume his former activities. He had then been well until a week before entry when he had had a similar but somewhat more severe attack. Two days before entry he developed left facial weakness, and also weakness of the left arm and leg. His systolic blood pressure which had been as high as 160 dropped to 110. Physical examination was not abnormal save for the paralysis. Laboratory data and the electrocardiogram were not remarkable. During his hospital stay of 16 days there had been a gradual diminution in the muscular weaknesses. Dr. Marshall Fulton pointed out that the patient was considered to have had a coronary thrombosis with a cerebral embolus originating from a mural thrombus.

The surgical case was presented by Dr. Hoerr. A 64 year-old Irish housewife had been perfectly well until 2 weeks before entry save for varicose veins which she had had since the age of 22. Two weeks before entry she had changed her home to an extremely "damp" locality, and at that time began to have pain and some swelling along the medial aspect of the left leg. This had persisted until the time of admission. Physical examination was not remarkable except for a series of tender hard lumps along the course of the left saphenous vein. Dr. Homans pointed out that this was the usual course of thrombosis in varicose veins. He gave a short discussion of the formation of thrombi. Appearing first as accumulations of platelets upon a vessel wall, these become matted together as a lamellated structure among the interstices of which white corpuscles adhere and a little fibrin is laid down. This is known as the white clot. When this clot becomes large enough to produce stasis, erythrocytes are deposited and the red clot is formed. There are several factors which predispose vessels to thrombosis. The first of these is trauma, infection or inflammation of a vessel wall or the tissues about the wall. Dr. Homans cited a case of 'milk-leg' in which extensive inflammation was found around the pelvic vessels. Another cause of thrombosis is depletion of blood as after severe vomiting or diarrhea. Yet a third cause is slowing of the blood stream—a condition commonly found in relaxed, dependent limbs. Such causes tend to induce thrombosis in sites particularly favorable—especially the upper femoral and external iliac veins.

The paper of the evening was by Dr. C. H. Best, of the University of Toronto, who described experiments in the use of heparin in the prevention of thrombosis. Knowledge of heparin began in 1916 with the work of Howell upon the mechanism of blood clotting. Heparin has been shown to antagonize the action of thrombin and to some extent the action of prothrombin. Dr. Best also pointed out the importance of the work of the chemists at the University of Toronto and elsewhere, who had purified heparin sufficiently so that it could be produced in crystal line form. Describing his own work, he demonstrated

three lines of experimentation. In the first, experimental thrombi were formed in the veins of animals by crushing the veins by the injection of a corrosive fluid (Sorian). Following this, some of the animals were treated with a constant intravenous infusion of saline in which crystalline heparin was dissolved. These animals showed much less tendency to form thrombi than did the controls, and if the original injury was not too great and if the treatment was kept up for several days, there even was healing of the vein. The second line of research consisted of microscopic examination of the changes in platelets in the process of forming thrombi. To illustrate this, Dr. Best showed motion pictures taken through oil immersion lenses. In these the platelets could be seen settling on a glass surface, then sending out digitating processes along the surface, and finally undergoing degenerative changes and fusion. The third group of experiments made use of glass loops inserted into the veins of animals, for example, connecting the carotid and the jugular veins. Thrombus formation was observed in these loops, and motion pictures were shown to illustrate this. These showed the formation of the white thrombi and also the breaking away of these thrombi to form emboli. When heparin was introduced into the circulation these thrombi no longer formed, and those thrombi which had formed remained without further growth.

Dr. Best then spoke briefly of the application of these findings to the postoperative treatment of surgical patients who had undergone serious operations. Greatly diluted heparin was allowed to run into a peripheral vein, at a concentration aimed to keep the clotting time at 15 or 20 minutes, for a period beginning an hour or two after operation and lasting about 5 days. The result in the cases so far studied in Toronto has been entirely satisfactory.

HAMPSHIRE DISTRICT MEDICAL SOCIETY

A special meeting of the Hampshire District Medical Society was called on Tuesday evening, January 18, to act upon the resignation of Dr. Francis E. O'Brien as secretary-treasurer and to elect his successor.

It was voted to accept Dr. O'Brien's resignation. Dr. Joseph D. Collins was unanimously elected secretary-treasurer, his appointment becoming effective at that date.

BROOKFIELD MEDICAL CLUB

The January meeting of the Brookfield Medical Club was held at Ye Olde Tavern in West Brookfield on Wednesday, January 19, with Dr. Charles A. DeLand, of Warren, host, and Dr. John Fallon, of Worcester, guest speaker, his subject being 'Observations on Recent Therapeutic Measures as Noted at the Mayo Clinic and Surgical Clinics in Chicago.'

The February meeting will be held on the third Wednesday, with Dr. Joseph Slowick, of Palmer, as host.

J. R. FOWLER, M.D., Secretary

NOTICES

BOSTON TUBERCULOSIS ASSOCIATION

The annual meeting of the Boston Tuberculosis Association will be held at the Copley Plaza Hotel, Copley Square, Boston on Tuesday, February 15, at 4 p. m.

Dr. Henry F. Vaughan, commissioner, Department of Public Health, Detroit, Michigan, will be the speaker.

NUMBER 6

THE ABSORPTION OF GLUCOSE FROM THE SMALL INTESTINE IN DEFICIENCY DISEASE

JUDA GROEN, MD *

AMSTERDAM, HOLLAND

IN A previous communication,¹ a simplified apparatus and technic for the study of intestinal absorption in man was described. The principle of the method, developed by Miller and Abbott,² consists in the occlusion of the upper part of the small intestine at a measured distance below the pylorus by a rubber balloon connected with the distal end of one of the two lumina of a rubber tube. The second lumen of the tube leads into a number of holes that open above the balloon. Through these holes 100 cc of 15 per cent glucose solution is introduced into the intestine, where it remains for half an hour, after which the remaining solution is removed by aspiration and repeated washings. The position of the tip of the tube, and thus the length (50 cm) of absorbing small intestine, is established by x-ray examination before the glucose is introduced. Adequate precautions prevent downward leakage and regurgitation into the stomach. Complete details of this technic are given elsewhere,¹ unless otherwise indicated, they will be referred to below as standard conditions.

It has been shown¹ that the amount of glucose absorbed from concentrated solutions under standard conditions in normal subjects is constant. Moreover, above a certain concentration (10 per cent) the amount of glucose absorbed is independent of the concentration of the solution introduced. Thus Cori's law³ has been confirmed for man. The normal absorption values under the standard conditions vary from 7 to 9 gm of glucose, averaging 7.77 gm. The age, sex and weight of the adult subject do not appear to have any detectable influence. Changes in the diet of relatively short duration do not affect the absorption rate.

RESULTS

The present observations are based on these facts, and deal with the absorption of glucose in pathologic conditions, with the standard technic. Mainly because the procedure of intestinal intubation requires a certain amount of co-operation on the part of the patient, the number of cases that could be satisfactorily examined was small. Of 13 patients, 3 (Cases 1, 2 and 3), had diseases of the alimentary canal in which diarrhea was an outstanding feature and had caused nutritional deficiency symptoms (anemia, pigmentation of the dorsa of the hands, smooth tongue). The other 10 cases exhibited deficiency disease of various types, without gross intestinal lesions, though in some instances with clinical evidence of intestinal dysfunction.

Glucose Absorption in Disease of the Intestine

One patient (Case 1), a sixty-year-old, white, single expressman, had been drinking heavily for twenty years. Four years before entry occasional vomiting and intermittent diarrhea began. Eighteen months before entry he began to lose appetite and weight. On admission he had a temperature of 101°F and showed emaciation and a dry scaly skin, pigmentation of the dorsa of the hands, atrophy of the lingual papillae, and a distended abdomen. He continued to have fever, and developed roentgenologic signs of infiltration in both upper lung fields and of fluid in the left pleural cavity. The liver was slightly enlarged. There was gastric anacidity after the injection of histamine. The Takata-Ara reaction was strongly positive and the patient had a moderate hypochromic anemia. Diarrheal stools showed an increased content of undigested starch and fat. Roentgenologic studies of the gastrointestinal tract were negative except for a somewhat dilated ileum and hypermotility of the colon. Ten weeks after

From the Thorndike Memorial Laboratory, Second and Fourth Medical Services (Harvard), Boston City Hospital and the Department of Medicine, Harvard Medical School, Boston.

Formerly Rockefeller Foundation Fellow and Research Fellow, Thorndike Memorial Laboratory, Boston City Hospital.

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY, FEBRUARY 7

MONDAY FEBRUARY 7

- *4 p m. Physicians and medical students are cordially invited to attend a clinic presented by the medical surgical and orthopedic services of the Infants and Children's hospitals in the amphitheater of the Children's Hospital

TUESDAY FEBRUARY 8

- *9 10 a m Boston Dispensary Follow up of interesting diagnostic problems presentation of former patients in the diagnostic hospital Dr Heinrich G Brugsch.
- *10 a m 12-30 p m Tumor clinic Boston Dispensary
- *8 15 p m Harvard Medical Society Peter Bent Brigham Hospital amphitheater (Shattuck Street entrance)

WEDNESDAY FEBRUARY 9

- *9 10 a m Boston Dispensary Hospital case presentation Dr S J Thannhauser
- *12 m Clinicopathological conference Children's Hospital Amphitheater
- 12 m Boston City Hospital Monthly clinicopathological conference Pathological amphitheater

THURSDAY FEBRUARY 10

- 8 30-9 30 a m Exchange visit surgical and orthopedic staffs of the Peter Bent Brigham and Children's hospitals held this week at the Peter Bent Brigham Hospital
- *9 10 a m Boston Dispensary Social service case presentation Mrs H B Hooker Miss E. Grundy

FRIDAY FEBRUARY 11

- *9 10 a m Boston Dispensary Emotional Factors in Asthma Dr Felix Deutsch.
- *10 a m. 12 30 p m. Tumor clinic Boston Dispensary

SATURDAY FEBRUARY 12

- *9 10 a m. Boston Dispensary Hospital case presentation Dr S J Thannhauser
- *10 a m. 12 m Staff rounds at the Peter Bent Brigham Hospital Conducted by Dr Henry A Christian

SUNDAY FEBRUARY 13

- 4 p m. Illustrated public health lecture, Faulkner Hospital auditorium Stomach and Duodenal Ulcer Dr Edward S Emery Jr
- 4 p m. Free public lecture. Harvard Medical School amphitheater of Building D Menstrual Disorders and the Menopause. (For women only) Dr John Rock.

*Open to the medical profession

tween 119 and 118 mg per 100 cc., averaging 134 mg

In the 6 patients (Cases 1, 2, 3, 4, 5 and 9) whose blood-sugar curve during the absorption was determined, a low sugar absorption was accompanied by a flat blood-sugar curve. The highest blood-sugar value obtained was 125 mg per 100 cc. after one hour, the lowest 88 mg. In some cases the blood sugar showed no rise above its fasting level. Figure 1 illustrates the upper and lower limits of the blood-sugar values in these patients com-

Figure 1 Upper and lower limits of blood-sugar values following introduction of 100 cc of 15 per cent glucose solution into a 50-cm segment of small intestine in normal subjects (solid circles) and in patients with defective absorption (Cases 1, 2, 3, 4, 5 and 9, open circles)

pared with the normal limits. The amount of glucose absorbed apparently exerts a definite influence on the blood-sugar curve.

DISCUSSION

Impaired absorption from the alimentary tract in patients with diarrhea might be supposed to result entirely from too rapid passage of the intestinal contents to allow opportunity for normal absorption. The decreases in absorption demonstrated above cannot, however, have been due to diarrhea only, as the glucose solution necessarily remained above the balloon in constant contact with the same area of intestine. It is therefore clear from the nature of the technic that the absorptive function of the intestinal wall itself was impaired whenever glucose absorption was found to be diminished, not only in the patients with undoubted organic disease of the intestinal tract (Cases 1, 2 and 3), but also in those with pernicious anemia (Cases 4, 5 and 6) and in the patient (Case 9) with "alcoholic" polyneuritis and pellagra. Nevertheless, this feature may be only partially responsible for

certain clinical manifestations presented by patients with chronic diarrhea. Thus, loss of body weight and flat blood-sugar-tolerance curves obtained by the usual technic may also be due in part to defective absorption resulting from too rapid passage of material through the intestinal tract.

The occurrence of deranged intestinal function, including poor absorption in certain deficiency diseases with prominent alimentary symptoms, has been suspected for some time.⁴ Pierce, Osgood and Polansky,⁵ Gál⁶ and Westenbrink and Overbeek⁷ have shown that rats given a diet deficient in one or more components of the vitamin-B complex absorb glucose from the alimentary tract at a slower rate than do normal controls. Trimble and Maddock⁸ found that dogs "in clinically unsatisfactory condition" had a diminished absorption. The work of Gross,⁴ McCarrison⁹ and Wheeler, Goldberger et al.,¹⁰ which has demonstrated pathologic changes in the intestinal mucous membrane of animals suffering from experimental nutritional deficiency, probably related to the vitamin-B complex, is also pertinent.

In certain human deficiency diseases severe intestinal disturbances occur. In the various forms of sprue the abundant fatty diarrhea and the excess of undigested starch in the stool justify the assumption of an impaired absorption. Less frequently, patients with pellagra, pernicious anemia or other less clearly defined conditions arising directly or indirectly from nutritional deficiency may show similar features.

Poor absorption, especially of glucose, has been assumed by many authors to exist in sprue. Thyssen^{11, 12} was among the first to point out that patients with sprue or celiac disease show only a very small rise in blood sugar after the ingestion of 50 or 100 gm of glucose by mouth. He doubted, however, whether this abnormal sugar-tolerance curve was due to poor absorption, as he also found abnormally flat curves after intravenous administration of glucose. Other observers,^{13, 14, 15} however, including ourselves,^{16, 17} have found that blood-sugar curves in sprue after intravenous administration of glucose are uniformly normal. Thus the conclusion is logical that the flat curve following the oral administration of glucose is probably caused by a slow absorption from the diseased intestine. In a certain proportion of cases of sprue the oral administration of large amounts of liver extract is relatively or wholly without effect on blood production as compared with the parenteral administration of the same material in usual doses.^{18, 19} Mackie and Pound²⁰ and Mackie, Miller and Rhoads²¹ have demonstrated abnormalities of the intestinal pattern by x-ray examination in cases of sprue and of so-called vitamin-B deficiency.

entry the patient died, and an autopsy disclosed tuberculosis of the lungs, intestine and peritoneum with marked involvement of the mesentery and its lymph nodes, and fatty degeneration of the liver.

Another patient (Case 2), an intelligent, sixteen-year-old Jewish boy, had suffered from diarrhea and intermittent bouts of fever for seven years. He had failed to grow normally, being only 4 feet, 7 inches tall and weighing only 59 lb. The tongue was smooth, the fingernails were small, and there was no pubic or axillary hair. The liver and

spleen were enlarged. The stools contained much mucus and an excess of soaps and undigested starch. The stomach contained free hydrochloric acid. Roentgenologic studies of the gastrointestinal tract showed narrowing of the distal portion of the ileum and of the ascending and transverse portions of the colon. There was a marked hypochromic anemia. This case was considered one of severe chronic ulcerative colitis.

The third patient (Case 3) had moderately severe nontropical sprue with diarrhea.

As determined by seven separate observations on these 3 patients, there was a definite decrease in glucose absorption under standard conditions. As Table 1 shows, the values obtained were 2.85 to 4.85 gm., which is significantly below the normal range of 7 to 9 gm.

Glucose Absorption in Deficiency Disease Five patients with typical pernicious anemia (Cases 4 to 8) were studied, of whom 3 (Cases 4, 5 and 6) were tested both before and during remission induced or maintained by liver-extract therapy. All 3 patients showed a diminished absorption during the active stages of the disease and a return to normal after effective treatment. One patient (Case 8) was examined only during remission and had a normal absorption, as did another (Case 7) in mild relapse with 3,000,000 red-blood cells per cubic millimeter.

A patient with chronic alcoholism (Case 9), showing both polyneuritis and pellagra, had a diminished absorption which became normal after he had been successfully treated for three weeks by injection of liver extract, a nutritious diet and

autolyzed yeast. Two patients (Cases 10 and 11) with "alcoholic" polyneuritis were examined after treatment and had a normal absorption of glucose.

In contrast to the observations on these 8 cases, in which the deficiency may be related to some factor associated with or related to the vitamin B complex, are the results obtained in 2 patients with relatively pure scurvy (Cases 12 and 13). Both showed a normal absorption of glucose.

The data for the chief observations under standard conditions in all 10 patients are shown in Table 2.

Dilution inside the Intestine In the normal subjects,¹ the 15 per cent glucose solution that had been introduced into the intestine was diluted while absorption was going on by a stream of fluid moving into the lumen. After half an hour the concentration of the glucose solution was found to vary between 3.24 and 2.11 per cent, with an average of 2.50 per cent, or about half the osmotic concentration of the blood plasma. The calculated osmotic pressure of the glucose, plus that of the

chlorides and their cations recovered in the diluted glucose solution, was found to be approximately equal to that of the blood plasma. Apparently the normal intestine adjusts its contents so that the final total concentration inside its lumen is in osmotic equilibrium with the blood plasma.

With one exception, this diluting capacity of the pathologic intestine, as in the normal individual, was undisturbed. Indeed, unusually large amounts of isotonic fluid were recovered from the bowel half an hour after the introduction of the glucose. The exception was a patient (Case 6) in whom the glucose concentration half an hour after the introduction of the 15 per cent glucose solution was 3.60 per cent.

Blood-Sugar Values In the normal subjects¹ the blood sugar was found to rise while glucose was being absorbed from the upper part of the intestine. A fairly typical curve could be constructed that reached its peak after half an hour or an hour. At the peak of the curve the blood sugar was be

unsatisfactory diet, but there was no special restriction in the quantity of carbohydrate taken

Nonspecific Effect The poor absorption in our cases might be a nonspecific effect due to the fact that almost all the patients had poor appetites and had been taking only small amounts of food and fluids over a prolonged period before the tests were carried out. The poor absorption, in other words, might be the result of a prolonged undernutrition, by which the intestine had lost its ability to absorb a relatively large quantity of glucose such as was administered for the tests. The diminished absorption might also be considered as a nonspecific phenomenon resulting from the general ill-health of the body. These explanations cannot be entirely refuted. Cori³ has shown that the absorption rate of glucose in the rat decreases markedly after forty-eight hours of starvation. Also, as mentioned before, a flat glucose curve similar to that seen in sprue is found in cases of general undernutrition.

We⁴ have been able to perform absorption tests after complete starvation in 2 patients with epilepsy who were otherwise normal, so far as could be ascertained by clinical examination. One of these patients fasted for forty-eight hours, the other for ninety-six hours, the water intake was not restricted during these periods. At the end of the starvation period both showed a normal glucose absorption. It may be argued that forty-eight hours of starvation for the rat is a relatively more prolonged period than a four-day fast for a human subject, and that the starvation period was too short to allow alterations to occur. We have, however, other indications that the decrease of absorption in our patients must be more specific. Both patients with scurvy who were examined had taken a diet that consisted mainly of bread and of lean, excessively cooked meat, a diet deficient at least in vitamin C but not in caloric content. Both had a normal absorption rate of glucose. The caloric content of the diet had not been particularly low in 2 of the cases of pernicious anemia. It seems unlikely, therefore, that a deficient caloric intake or nonspecifically unbalanced diets can account for the impaired absorption found in our patients.

Vitamin-B Complex On the other hand, the 5 patients (Cases 4, 5, 6, 7 and 9) with diminished absorption fell into the group of vitamin-B-deficiency disease, if one may so consider pernicious anemia and "alcoholic" polyneuritis. In common with patients having pellagra and sprue, such patients frequently present evidence of derangement of the alimentary tract manifested as glossitis, achlorhydria or diarrhea. The parenteral administration of a fraction of liver soluble in 70 per cent

alcohol has been shown in each condition to cause prompt improvement of lingual and intestinal symptoms, and if macrocytic anemia is present to result in characteristically increased blood production. In many cases similar effects are obtained with hog-stomach preparations or with mixtures of beef muscle or autolyzed yeast with normal human gastric juice.^{22, 23} In some instances the administration of beef muscle or autolyzed yeast preparations alone produces such effects.¹⁹ These observations have been made while the patients were being maintained on diets devoid of power to induce remission in pernicious anemia. Such diets have contained no meat, fish or eggs and have consisted largely of refined carbohydrates. According to Castle and his associates,^{22, 23} the basis of these effects on blood production and glossitis is the presence in liver-extract preparations of a substance or substances produced in vivo from beef muscle or autolyzed yeast (extrinsic factor) by a constituent of the normal gastric secretion (intrinsic factor). Depending on the natural presence of intrinsic factor in the gastric secretion of the patient, a response to beef muscle or autolyzed yeast alone will be obtained. The administration of hog-stomach preparations supplies the extrinsic as well as the intrinsic factor.

It is proper to assume, at least for the purposes of this discussion, that pernicious anemia, sprue, pellagra and "alcoholic" polyneuritis are deficiency diseases due either to a direct deficiency in the diet,³⁰ or to a virtual deficiency conditioned by failure of gastric secretion or of intestinal absorption of one or more substances belonging to or closely associated with the vitamin-B complex.^{23, 31*} At any rate, it is clear that in each of these conditions under controlled dietary circumstances the parenteral administration of liver extract has been shown to have a promptly beneficial effect on glossitis and on blood formation. In many instances the effect on diarrhea is scarcely less striking.

A therapeutic test consisting of the administration of the vitamin B complex alone or with gastric juice, all other conditions remaining unchanged, could not be carried out on our patients. When treated in various ways, however, some by injection of liver extract, some by mixtures of gastric juice and various sources of extrinsic factor by mouth, all showed clinical improvement. Shortly an increase in appetite took place, and eventually the patients ate more and better food than they had ingested before treatment. The intake of fluid also increased. It is therefore impossible to conclude exactly what constituent caused the im-

*In this communication the designation vitamin B complex is given to a group of substances, constituents of liver meat yeast and so forth, that are soluble both in water and in alcohol and are necessary for the promotion of growth and for the prevention of changes in the skin, tongue, nervous system and blood of mammals. It includes the antineuritic vitamin flavin, George & B. Castle's extrinsic factor and probably other substances.

The existence of impaired absorption also suggests itself in those cases of pernicious anemia which require unusually large amounts of liver extract administered by mouth for their recovery or maintenance. Castle and his associates,²²⁻²³ for example, have presented evidence of this type, and consider that the presence of intestinal stenoses or short circuits may, through interference with absorption, account for the development of macrocytic anemia responding to the parenteral administration of liver extract. The association of the clinical manifestations of pellagra, beriberi and vitamin-A deficiency with disorders of the intestinal tract also suggests malabsorption. Keefe and his associates²⁴⁻²⁵ have noted the development of both hypochromic and macrocytic anemia and signs of vitamin-A-deficiency disease in cases of chronic dysentery. In many of these patients, however, the presence of intestinal lesions was associated with more or less restricted dietary regimes. Heath and Fullerton²⁶ have shown that the absorption of potassium iodide is sometimes greatly delayed in dietary deficiency conditions. The increased tolerance to galactose in pernicious anemia observed by Donath²⁷ and by Singer and Wechsler²⁸ has been ascribed to a slow absorption of this sugar from the alimentary canal.

In spite of the foregoing evidence, however, the existence of a diminished absorptive power of the intestinal wall in human deficiency disease needed proof by a direct test capable of excluding the possible influence of increased intestinal motility. Blood-sugar curves and excretion tests performed in the usual manner are all subject to other metabolic influences than absorption alone. The abnormal results of these tests, therefore, did not necessarily indicate a diminished absorption. However, any influence of increased motility of the intestine or of interfering metabolic factors was excluded by the technic employed in our experiments. They constitute apparently the first *direct* demonstration in man that the passage of material through the wall of the small intestine may be impaired in deficiency states. There is no doubt, therefore, that the flat blood-sugar-tolerance curve in sprue, in anemias from direct or indirect dietary deficiency, and in malnutrition is due, at least in part, to physiologic or pathologic changes in the absorbing mechanism per se. At the same time it should be borne in mind that our experiments deal with glucose only, an unpaired absorption of this sugar does not necessarily imply that other substances are also absorbed at a slower rate. Since glucose is a readily diffusible substance, however, it is reasonable to suppose that substances of greater complexity or of larger molecular weight would

encounter even greater difficulty. This does not imply what is clearly not the case, that the process of absorption is purely a matter of diffusion. It may at present be regarded as a likely supposition that the absorption is defective in deficiency diseases such as sprue, pellagra and pernicious anemia, and in less well-defined deficiency conditions presenting similar manifestations of the alimentary tract. The explanation of this poor absorption requires further consideration.

Achlorhydria apparently does not significantly affect glucose absorption. A patient (Case 2) with diminished absorption secreted free hydrochloric acid. The cases of pernicious anemia in which the absorption returned to normal after treatment still had gastric achlorhydria. One patient (Case 10) who had a normal absorption was known to have had a histamine-refractory achlorhydria of at least two years' duration. Moreover, it was found in normal subjects¹ that the addition of 0.1 normal hydrochloric acid to the glucose solution actually lowered its absorption rate.

Anemia The decrease in absorption could not be explained by the level of the hemoglobin or of the red-blood cells. A patient with "alcoholic" polyneuritis (Case 9) had no anemia, yet showed a definitely decreased absorption. A patient with anemia due to deficiency of vitamin C (Case 12) had a normal absorption.

Adaptation Westenbrink²⁹ has adduced evidence that the absorptive capacity of the intestinal canal is able to adapt itself to the constituents of the food. When rats were fed on a mixture containing glucose as the main carbohydrate, the absorption rate for glucose increased and that for galactose decreased. When the rats were fed on galactose the reverse took place. When they were fed on a diet rich in fat, the absorption for all carbohydrates diminished markedly. According to Westenbrink, the decreased glucose absorption in vitamin-B deficiency is not specific but is the result of the decreased appetite of the animal and the subsequent lower intake of carbohydrate.

To test Westenbrink's explanation on man, we have tried the effect of changes in diet of normal subjects upon the absorption of glucose. No change could be found when the relative amounts of carbohydrate and protein in the diet were varied. One of the subjects took a ketogenic diet containing only 25 gm of carbohydrate for ten days. No diminution in the absorption of glucose was found at the end of this period.¹ We therefore find it hard to ascribe the decreased absorption in our patients to a loss of adaptation. It is true that the history of our cases revealed poor appetite and an

A PLASTIC OPERATION FOR THE CORRECTION OF HYPERTROPHY OF THE BREAST

HORACE K. SOWLES, M.D.*

BOSTON

HYPERTROPHY of the female breast is not an uncommon affliction. It usually involves both breasts, but occasionally it is unilateral. The increase in size is caused partly by an increase in the amount of fat, but may also be accompanied by a variable degree of actual hypertrophy of glandular tissue. Increased obesity often seems to add disproportionately to the size of the breasts, and dietary measures offer only partial relief.

The degree of pendulousness is sometimes increased by lactation, often the patient has strapped her breasts down with a tight brassière in an effort to make them less conspicuous, and this has caused more or less elongation. These large breasts are a source of considerable discomfort, first because of their heavy weight, and further because of the inconvenience of the various types of support designed to hold them in position. Many patients have complained of tight brassière straps over the shoulders, which sometimes cause pain there, occasionally extending down the arms. The excessive weight often causes faulty posture, the patient assuming a slight stoop in an unconscious effort to conceal the breasts and make them less conspicuous. A certain amount of concealment can be accomplished through dress, but even the most skillful designer may fail to obtain the desired result, so that the patient feels deprived of the privilege of wearing certain types of gowns. Finally there is the problem of mental attitude.

Read before the annual meeting of the New England Surgical Society, October 2, 1937, at Providence, Rhode Island.

From the Surgical Service of the Massachusetts General Hospital, Boston.
Assistant visiting surgeon, Massachusetts General Hospital.

Some patients are so sensitive and self-conscious about what they feel to be their deformity that they are definitely handicapped in their social contacts, and deprive themselves of many normal activities in which they would otherwise take an active interest.

The accompanying photographs (Figs 1-5) demonstrate what can be accomplished by plastic surgery. These 5 cases were selected from a group of 15 to represent the different types which may be encountered. A few facts regarding the cases are as follows:

Case 1 A married woman of 35. She had had one child, who was breast fed. The breasts were long and pendulous, with only a moderate amount of fatty tissue. The postoperative photographs were taken 6 months after operation.

Case 2 A married woman of 34 who had had three children. All were breast fed. She had very heavy breasts, composed not only of hypertrophied gland tissue but also of an excessive amount of fatty tissue. The postoperative photographs were taken 6 months after operation.

Case 3 A single woman of 25 who had very heavy breasts composed largely of hypertrophied gland tissue. The postoperative photographs were taken 6 months after operation.

Case 4 A single woman of 30. Both breasts were heavy, but there was a very marked glandular hypertrophy on the left side. A plastic operation was done on both breasts, and the postoperative pictures were taken 10 days later. It should be noted that the breasts are quite high, on palpation they were very firm, with areas of induration caused by postoperative inflammatory reaction (some of these areas persist for several months, but eventually disappear).

provement of absorption during remission in these particular cases. By analogy with other clinical observations¹⁹⁻²³ under controlled conditions referred to above, however, the cases may reasonably be classed as either direct or conditioned vitamin-B-complex deficiency diseases, and may be presumed to have responded favorably to the administration of such substances either in specific therapeutic preparations or in the food included in the improved diets.

Castle²² has pointed out with reference to the development of pernicious anemia that in a patient with progressively diminishing power of secretion of the intrinsic factor a point would be reached where the extrinsic factor (vitamin-B complex) would no longer be effective in producing adequate amounts of liver extract. This result would diminish the patient's intake of the extrinsic factor through loss of appetite, and thus a vicious cycle would be established, leading to progress of the disease. We wish to suggest that in addition the vicious cycle would involve progressive decrease of the absorptive capacity of the intestine. Not only glucose but other substances might be absorbed with difficulty. If the diet taken by the patient were already poor in vitamin-B factors, poor absorption would decrease the utilization of even this small amount, or of any products of its interaction with residual amounts of the intrinsic factor. At first the intestine may be able, because of its great length, to compensate to some extent for the diminished absorption per unit of surface. In this stage, liver or stomach preparations given by mouth are still to some extent effective and may induce a remission. If intestinal absorption is further impaired, however, or if some additional circumstance (infection) interferes, therapy by mouth may require extremely large amounts of material in order to be effective. Some cases of pernicious anemia, and especially cases of chronic sprue, are apparently almost totally refractive to oral therapy owing to this absorption barrier. Parenteral administration of liver extract should then be resorted to in order to break the vicious cycle.

SUMMARY

By means of a simplified technic of intestinal intubation which had been previously standardized on normal individuals, the absorption of glucose was studied in 3 patients suffering from organic disease of the intestine associated with diarrhea, namely, 1 case of tuberculous enteritis, 1 of ulcerative colitis and 1 of nontropical sprue. In each case decreased absorption was demonstrated.

Among 10 patients with various dietary deficiency diseases, diminished absorption of glucose was found before treatment in 3 cases of pernicious anemia and in 1 case of "alcoholic" polyneu-

ritis with pellagra. Absorption of glucose in these 4 cases returned to normal after treatment. The absorption of glucose was found to be normal after treatment had been applied in 1 additional case of pernicious anemia and in 2 additional cases of "alcoholic" polyneuritis. However, 2 cases of scurvy before treatment showed a normal absorption of glucose.

Since by the nature of the experimental method the glucose solution was maintained in contact with the same portion of the upper small intestine, the diminished absorption was clearly due to defect of the absorptive capacity of the intestinal wall and not to unusually rapid passage of the intestinal contents. In those cases in which the absorption of glucose was diminished, the blood sugar showed a smaller rise during the absorption test than in control observations on normal subjects. The flat blood-sugar-tolerance curve often found in sprue, and sometimes in pernicious anemia and certain other dietary deficiency states, is therefore attributable, at least in part, to a diminished absorptive power of the intestine.

The decreased absorption of glucose in deficiency disease may be a nonspecific phenomenon, perhaps the result of an insufficient caloric supply over a long period of time. It is more likely, however, to be a specific effect due to a lack of some component or metabolic derivative of the vitamin B complex.

The author expresses his appreciation to Dr W O Abbott, Dr G W Karr, Dr C M. Jones, Dr H. C. Trumble and Dr W B Castle for advice and encouragement in the course of the work.

Nicolaas Maesstraat 120, Amsterdam, Holland.

Case 5 A single woman of 26, who had a marked glandular hypertrophy of the left breast. A plastic reconstruction was done. The postoperative photographs were

Preoperative

Postoperative

Figure 5 *Case 5*

taken 5 months later. The normal right breast was of the pointed type, which is difficult to duplicate by operation; however, the side view of the reconstructed breast is satisfactory.

The operation which I have done on these patients is a modification of the Biesenberger¹ procedure, as given in his small but comprehensive book covering plastic and cosmetic operations on the breast. The operation, which he advocated as the most satisfactory, was accomplished by a complete dissection of the skin from the glandular tissue, care being exercised to preserve the nipple with its areola. He then excised the excessive glandular and fatty tissue in order to reduce the breast to the desired size. The breast was reconstructed and sutured to the chest wall, the skin then being fitted around the breast and the excess skin excised at the lower margins. For the details of the operation which I have done I am indebted to Dr Yolande Huber, of New York City. I have carried it out as follows:

First, a circular incision is made around the nipple at the outer margin of the areola, or if the areola is too large, this incision may be made

within it. Another circular incision is made about 0.6 cm outside the first circular incision. From the lower margin of this outer circle a vertical incision is made down to the submammary fold in the skin below the breast. A horizontal incision from 7 to 10 cm long is then made along this fold, the skin flaps are carefully dissected from the breast tissue so as to leave the areola and the small ring of skin around it intact, the ring of skin serving temporarily to protect the areola against injury from manipulation. A moderate amount of fatty tissue is left on the under surface of the skin in order that no damage may be done to the circulation of the skin flaps. The entire gland is uncovered so that the pectoral muscle or the chest wall is exposed on all sides of the breast. The breast is then grasped by the apex, and segments of fat and glandular tissue are excised. This excision begins at the areola margin and is carried down to the chest wall, several segments may be removed until the breast is reduced to the desired size. It now appears as a long, thin mass of glandular tissue with the nipple and areola at its apex. In order to reconstruct this into a rounded mass, it is necessary to rotate it upon itself, suturing the folds to each other and suturing the margins to the chest wall. For this purpose fine silk sutures are used. The proper level for the upper margin of the breast is the second rib. The amount of rotation may be as much as 180 degrees. The extra ring of skin around the areola having served its purpose of protecting, is excised, and the skin flaps are carefully fitted around the reconstructed breast. It will be found necessary to excise a considerable amount of skin at the lower borders. No attention is paid to the areola until after the skin has been fitted and sutured. The opening for it is then made at the upper end of the vertical suture line. This opening is circular, and should be at least 2.5 cm wider than the contracted areola, so that when the latter is sutured to the margins of the opening it will be stretched to its normal size.

It is difficult to describe the operation adequately, but the accompanying group of outline drawings (Fig 6) in connection with the text will help one to visualize the successive steps.

The postoperative dressing is very important. A liberal amount of gauze dressing is used and over this plenty of sheet wadding, a scultetus swathe is then applied in such a way that it fits firmly and smoothly. Each tail is pinned to prevent loosening, and shoulder straps are attached to prevent slipping. A carefully applied elastic bandage may

are notoriously poor as milk-producers. No one of my patients has yet been through a pregnancy, but in all cases both the glandular tissue left behind and the ducts leading to the nipple have been uninjured. I see no reason why these breasts should not function normally, or at least nearly as well as they would have if the operation had not been done.

DISCUSSION

DR. GEORGE C. WILKINS, Manchester, New Hampshire. Evidently the women in my locality with large breasts accept the condition with a certain equanimity, at any rate they do not apply to me for relief. The operation described by Dr. Sowles is a very clever one. I know the principles of one or two other procedures in which the skin about the nipple is slid up under a bridge of skin and most of the lower part of the breast is removed. Technically, his method is of course far superior to these, but its success appears to depend entirely upon the most scrupulous attention to details.

DR. CHARLES L. LARAIN, Waterbury, Connecticut. I com-

pliment Dr. Sowles on the splendid results he has obtained. He has emphasized the importance of adequate support of the reconstructed breasts by a properly fitting dressing. I have found that a 3-inch Ace or Bender bandage applied over the breasts and around the thorax in a figure eight

will satisfy all the requirements. It holds the breasts up snugly, allows the patient to breathe easily, and will stay in place for a week or ten days, especially if affixed at the edges with strips of adhesive tape running anteriorly upward over the shoulder and then posteriorly downward.

A NOTE ON RACIAL INCIDENCE IN PORTAL CIRRHOSIS

WYMAN RICHARDSON, M.D.*

BOSTON

FOR some time I have suspected that Italians are peculiarly subject to cirrhosis of the liver. In order to verify this impression, the records of all Massachusetts General Hospital ward patients, during the years 1928 to 1935 inclusive, where the diagnosis of portal cirrhosis appeared, were studied. All cases in which there was a reasonable doubt of severe liver disease, as determined by the usual clinical data, were excluded. A total of 48 cases of portal cirrhosis was gathered. Since there were autopsies in only a few cases, no further attempt was made to differentiate the type of cirrhosis, it being practically impossible to do so without pathological examination. However, all cases suggesting the biliary type of cirrhosis, and all cases with positive blood Hinton or Wassermann tests, were excluded.

The racial incidence among these 48 cases in the total hospital population is indicated in Table 1. It will be noted that 19, or 39.5 per cent, of the 48 cases of portal cirrhosis occurred in native-born Italians, whereas this racial group accounted for

only 7.3 per cent of the total hospital population. The incidence of cirrhosis in each of the other groups, including individuals born in the United States of Italian mothers, was lower than that in the total hospital population. Although this is a

Associate physician, Massachusetts General Hospital.

be used instead of a swathe. The dressing is left undisturbed for one week.

I have, on several occasions, done this reconstruction operation on both breasts at one sitting, but the procedure is long and tedious, taking from three and one half to four hours. With in-

postoperative dressing reduces this hazard. Only once have I found it necessary to evacuate serum through a corner of the incision, and only once was it necessary to drain an infected hematoma.

This type of operation appears to give the best cosmetic result. In some of the other operations

Figure 6

Drawing A shows the skin incision in heavy ink. Drawing B shows the beginning of the elevation of the skin flaps. Drawing C shows the breast entirely uncovered down to the chest wall on all sides. In Drawing D the breast is grasped at the nipple and segments are excised from the edge of the areola to the chest wall. In Drawing E, by rotating the gland, a round conical breast is reconstructed, the folds are approximated to each other with fine silk sutures and the margins of the breast are

sutured to the chest wall, the upper border being held at the level of the second rib, the extra ring of skin around the areola is then excised. In Drawing F, the skin is fitted around the breast from above downward, the excess being cut away in the midline and below. The areola is temporarily covered. In Drawing G the opening for the areola is made. Drawing H shows the appearance at the end of the operation.

creased experience in this procedure, I now advise a two-stage operation, with ten days between the first and second stages. I believe this is safer for the patient and probably reduces the chances of infection, although it necessitates the discomfort of two administrations of anesthesia and a ten-day increase in the hospital stay.

As to complications, the extensive elevation of skin predisposes to collections of blood or serum under the flaps, but care in the application of the

described in the literature, all the tissue is removed from the lower or outer side of the breast. To be sure, this reduces the size and weight, but the end result is a flat type of breast. With the operation described above, the breast is actually reconstructed into a round juvenile type of any desired size, and is then sutured at the correct level to the chest wall.

The question of the possibility of future lactation has been raised. Large, hypertrophied breasts

edly enlarged (Fig 2) and the joint cavity was tense with fluid. A definite mass was palpable over the dorsum of the foot at the astragaloscapoid junction. The circumference of the left ankle was 8.8 cm. greater than that of the right. There was an increase of 6.9 cm. at the mid-tarsal level of the left foot. All motions of the foot and ankle were limited to 50 per cent of normal. There was moderate tenderness on deep pressure and on forced ankle motion. The ankle joint was not unstable, and no grating was perceptible by either palpation or auscultation. The skin was normal in appearance, and there were no signs of infection or of inflammation.

Examination of the blood showed a hemoglobin of 90 per cent, red-blood cells numbered 4,840,000 and the white

Figure 3 *Later x-ray film showing a definite mass on the dorsum of the foot resembling an osteochondroma*

cells 8400. The blood Hinton and Wassermann tests were negative, the urine was negative. The blood calcium was 9.2 mg per cent, phosphorus 4.8 mg per cent, phosphatase 0.51 K units. The spinal fluid was clear, with 4 cells per cu. mm., the pressure and statics were normal, the Wassermann and colloidal gold tests were negative. The Mantoux test was positive at 1:5000. X-rays showed destruction and fragmentation of tarsal scaphoid with proliferation also proliferation of calcaneal epiphysis (Fig 3), the diagnosis was neurotrophic arthritis or atypical Koehler's disease.

The joint was tapped, and about 2 oz. of thick clear fluid was removed. Examination of the joint fluid showed a cell count of 1200. 52 per cent clasmotocytes, 28 per cent monocytes, 16 per cent polymorphonuclears, 4 per cent lymphocytes. Cultures showed no growth. A gonococcal complement fixation test and a Wassermann test were negative. A guinea pig injection was negative for tuberculosis.

At biopsy, a thickened synovial membrane was seen, and a large movable cartilaginous mass was found at the junction of the astragalus and the scaphoid. Portions of the synovium, the mobile mass and joint detritus were removed for study. No indication of infection was present. The pathological report was chronic synovitis, islands of cartilage, some of which are being replaced by bone some new bone formation with fibrosis of the marrow

no evidence of tumor or tuberculosis, no growth on culture.

In order to determine deep sensibility, three rows of intradermal blebs were made with 1 per cent novocain from the mid left leg down and over the ankle and foot. One row was anterior, and the others were somewhat medio-posterior and lateroposterior. After superficial anesthesia was obtained, a sharp-pointed needle was passed through each bleb into the deep tissue. The charted results showed a definite decrease in deep sensibility, beginning at the level of internal malleolus and extending over the ankle and foot to the level of the base of the metatarsals. Deep insensibility to pain was nearly complete, but the patient felt definite deep-pressure sensation upon needle insertion. The reactions of the right foot and ankle were normal as checked against two controls. These changes in sensitivity may have been caused by chronic distention of the capsule and synovium. As a rule, little deep pain is complained of by patients when having a distended joint aspirated.

In order to substantiate the impression that the condition was caused by persistent trauma to an unprotected insensitive joint, the joint fluid was aspirated and measurements of the ankle were recorded. A Boehler walking cast was applied, and upon its removal 5 weeks later further measurements were made. There was a decrease in the circumference at the level of the scaphoid of 3.8 cm. This evidence was supported when the patient secured permission to return to school for 10 days with the ankle unsupported. He returned at the end of that time with the joint filled with fluid.

The neurological examination was essentially negative. No stigmas of hereditary degenerative diseases of the nervous or skeletal system were found. The joint was neither painful nor abnormally mobile. This may have been a neurotrophic joint, but the absence of neurologic abnormalities elsewhere is against it. The staff concluded after a study of the x-rays and clinical evidence that the condition was one of degenerative fracture of the scaphoid, with subsequent proliferation and displacement of the astragalus.

In a familial neuropathy study the blood serologic tests, spinal tap and neurological examination of the mother were negative. The previous hospital records of a brother were negative for any central nervous-system complications.

On summing up the information concerning this patient, one feels confident that the condition was neuropathic. Yet confirmation by positive serologic or neurologic changes is desirable, it not essential, for a definite diagnosis. The question remains, Just when is an apparently neuropathic joint sufficiently neuropathic to warrant a final diagnosis as such?

In an effort to avoid an untenable diagnosis we carefully considered a thorough differential. Since within the astragaloscapoid joint—as noted at biopsy, it was not separated from the ankle joint proper—there was a movable mass, diseases which produce such a lesion was considered. Osteochondritis dissecans and osteochondromatosis were ruled out by x-rays and by examination of the joint and its tissues at biopsy. Chronic infectious arthritis, particularly that caused by the tubercle bacillus, could not be considered in the light of the sterile fluid, lack of inflammatory reactions, and negative

It is difficult to account for this apparent racial tendency to develop portal cirrhosis. One naturally associates the disease with the prolonged, though not necessarily excessive, use of alcoholic beverages, and the Italian habit of drinking a peculiar type of red wine may be a possible etiologic factor. The fact that all but one of the patients

were born in Italy is interesting, for undoubtedly the drinking habits of the group born in the United States of Italian mothers are quite similar to those of the Italian-born group. Possibly the former have not yet reached the age when cirrhosis is likely to occur.

264 Beacon Street.

AN UNUSUAL CASE OF PAINLESS SWELLING OF THE ANKLE

RUSSELL F. SULLIVAN, M.D.,* HAROLD M. CHILDRESS, M.D.†

BOSTON

PAINLESS swelling of a joint caused by tabes dorsalis or syringomyelia is not infrequent but when a similar joint lesion occurs without demonstrable neurologic or serologic changes, the condition may be classed as a rarity. Interest in this case centers not only upon the pathologic changes in the joint and the primary and secondary factors producing it, but also upon the making of a definite diagnosis. The question arises whether one is justified in calling such joints neuropathic if other evidences of neural lesions cannot be found.

CASE REPORT

The patient, a white male, aged 16, was seen at the Boston City Hospital, November 3, 1936, and complained of painless swelling of the left ankle. He stated that in

x rays showed a questionable old fracture of the scaphoid with proliferation. He refused further treatment when he was advised to enter the hospital for complete examination. For the next 6 months, he said, he attended school as usual and had no pain in the ankle, but the swelling remained about the same. On February 17, 1936, he was admitted to a local hospital and was subjected to thorough study. Two examiners from the neurologic staff found a diminished sensation to heat, cold and pain over the superficial distribution of peroneal nerves on the left, and to some extent on the right. They decided that this indicated syringomyelia. The patient was discharged 6 weeks later with that diagnosis, and with an arch support for the left foot.

Figure 1. X-ray film taken shortly after the original injury and showing a lesion in the vicinity of the scaphoid, which was diagnosed as a possible fracture.

mid August, 1935, he had sustained a slight injury to the ankle when he vaulted over a 5-foot fence. It became swollen, but he was able to walk with only moderate discomfort. The day following the injury he attended the outpatient clinic of this hospital, when x rays were taken (Fig. 1) and the ankle was strapped with adhesive. The

Figure 2. Appearance of ankle approximately fifteen months after injury.

This support was discarded in a few weeks. He stated that until his admission, approximately 15 months from the date of injury, he had been performing his usual duties at home and at school without discomfort. The affected ankle, however, had become more enlarged during the last 4 months, and he had been aware upon walking of a vague sensation in that joint.

There was no family history of tuberculosis, cancer or insanity. The patient's health had always been good except for measles, mumps and chickenpox in childhood. On physical examination the left ankle appeared mark-

†Former resident, Bone and Joint Service, Boston City Hospital.

patients who were treated by splinting, by full protection and later by physiotherapy made complete recoveries. Philips and Rosenheck¹⁴ report in 2 patients three apparently neuropathic joints which appeared after localized trauma. In each case the usual progressive neuroarthropathy was found despite the absence of any positive blood, spinal fluid or neurologic changes. One patient, an ice carrier, sustained a severe strain of his shoulder. The man was dissatisfied with conservative treatment and went to another hospital, where a biopsy gave a negative report for tumor. Later his other shoulder showed a slight but similar affection, but both joints reached a quiescent stage and he was able to work without discomfort or mechanical handicap. He was observed for over two years. The other case was that of a lumberyard worker who had a history of trauma of the shoulder joint. He had a neuropathic joint filled with sterile fluid. He also responded to conservative treatment, and the swelling and disability gradually decreased over the ten months of observation. These authors point out that Virchow found and reported such joint changes following peripheral nerve lesions, but that he received no credit for this discovery. They conclude that the explanation may be the result of a certain type of injury upon a peculiarly constituted individual who is disposed to such a condition.

That the lesion is rare is shown by the report by Key¹⁵ of 69 cases diagnosed as having neuropathic joints, all of which were proved to be definitely tabetic. Steindler² writes of 64 cases of which all but 2 were tabetic, these presumably being caused by syringomyelia. Campbell¹⁶ says that he has seen many patients in whom the brachial plexus has been injured, severed or avulsed but that in no case did such a joint develop. Others state that they have never seen this syndrome with peripheral nerve injuries. Milgram³ sums up the situation by asserting that if neuropathic joints do occur after such peripheral nerve trauma they must be extremely rare. According to him, analysis of most case reports shows that there have often been avulsions and tears of the cervical or dorsal roots, which might well be attended by associated injuries to the spinal cord. Philips and Rosenheck¹⁴ state that the condition may be a new clinical entity, that it is apart from the usual neuropathic joint, and that it occurs more frequently than is generally believed. They emphasize the importance of its recognition in the diagnosis and treatment of industrial injuries.

Codman¹⁷ agrees that in the patient here considered the neuropathy antedated the actual injury noted in the history and that thus the tarsal

bone must have been so predisposed. The loss of the sensory afferent fibers allowed the joint to become indolent, vulnerable to trauma and unable to compensate in case of injury. As noted in the early x-rays by the increased density of the calcaneal epiphysis and by the amount of destruction and proliferation of the scaphoid, one must conclude that so extensive a condition would not have been produced in three weeks. There is also a marked increase in inorganic salts in the other tarsals. Thus, unnoted by the patient, an insensitive left ankle joint must have been in existence for several weeks or months before the recorded trauma was received. It is well known that increased fragility of bone occurs in a neuropathic joint, and that of the tarsal bones the scaphoid is the most frequently affected. This is because of its exposure to such heavy pressure and strains in ordinary walking. From this fracture and subsequent fragmentation of the scaphoid there resulted such an imbalance in the usual weight-bearing lines that a defensive reaction was produced. This increase in size of both the distal tibia and fibula is common in neuroarthropathies, and Potts¹⁸ has given it the name of parosteal bone.

That the lesion was progressive is shown by the two x-ray plates, and that it was caused by the constant traumatization to an unprotected joint is shown by the marked improvement in the joint upon its being protected by the walking iron. That the neural mechanism is disturbed is evidenced by the slight pain present, which is not commensurate with what one would normally expect with such an extensive lesion. Eloesser¹⁹ has produced similar neuroarthropathies in cats by traumatizing the joint after he had severed the sensory fibers leading to the legs. The joint fluid is caused by a traumatic synovitis, and the partially loose bodies in the joint are pressed-out osteophytes, forming islands of bone in varying stages of development in the synovial folds and on the exposed articular surfaces.

The x-ray plates were seen and the facts of this history discussed by the staffs of one Boston and two New York hospitals. The roentgenologists made a positive diagnosis of neuropathic joint, the neurologists were inclined to defer final diagnosis until confirming evidence of some known neurologic factor was presented, the pathologists were unwilling to make further comment, other than that the joint showed chronic synovitis, with concurrent bone destruction and repair, the orthopedists called the joint neuropathic, advocated treatment by adequate splinting and protection, but preferred to have the condition linked with some recognized neuropathy.

results from guinea-pig injections. An atypical osteochondritis juvenilis of the tarsal scaphoid followed by its fragmentation, thereby creating a static imbalance in weight-bearing, was given credence when 2 painless cases of tarsal osteochondritis were found reported by Buchman¹. But the x-ray plates made three weeks after injury show such extensive combined bone destruction and reparation at the astragaloscaphoid joint and in the scaphoid that in no way could the condition be classed as Koehler's disease. The finding that absence of pain with such a lesion is indicative but not pathognomonic of neuropathic joints made the situation more confusing. Steindler² reports 16 out of 99 neuroarthropathies which had varying degrees of pain. Milgram³ also states that deep-tissue insensibility to needle puncture is not a constant finding in neuropathic joints, and that the occasional infection subsequent to biopsy is almost invariably accompanied by pain in that area.

Granting that the condition is typically neuropathic—which it apparently has been from the start to the present time—one is confronted with the necessity of explaining the neuropathogenesis. Mitchell⁴ in 1831 first described such joint lesions, but it remained for Charcot⁵ thirty-seven years later to make it a clinical entity by his complete description and his association of it with tabes dorsalis. During and immediately after the Civil War cognizance was given to the fact that traumatic injuries to the spinal cord or to nerve roots could produce exactly the same clinical and pathologic changes as those seen in a Charcot joint. To show the progress of this study since then and to apply it to this case, we give below the classification of neuropathic joints by Shands⁶. He places tabes dorsalis and syringomyelia in separate groups, as they are the causative factors in practically all cases.

- 1 Tabes dorsalis
- 2 Siringomyelia
- 3 Following lesions of the cerebrum
 - Dementia paralytica
 - Hemiplegia following hemorrhage.
- 4 Following lesions of the spinal cord
 - Injury
 - Congenital malformation
 - Tumor
 - Tuberculosis of spine.
 - Acute myelitis and anterior poliomyelitis
 - Progressive (central) muscular atrophy, etc.
- 5 Following lesions of peripheral nerves
 - Injury
 - Peripheral neuritis
 - Leprosy

In this patient one can eliminate cerebral lesions, and with the exception of trauma, all spinal lesions. Complete spinal plates at two hospitals

were interpreted as negative for either congenital or developed malformations. In considering the peripheral nerve lesions one may reject leprosy and peripheral neuritis by reason of the history and the clinical findings. There remain but the cord and peripheral lesions caused by trauma or by unknown or concealed factors. It is logical to consider only the peripheral nerve lesions, since the area of partial deep sensibility following trauma is sharply limited to the ankle and foot.

The first case of joint changes subsequent to peripheral nerve lesions was reported by Packard.⁷ Mitchell⁸ wrote of a patient who developed excessive joint changes after dislocation of the humerus. McArdle⁹ mentions that arthritic changes may appear when a nerve to that joint has been pierced, rubbed, lacerated or otherwise subjected to trauma or irritation. It is known that atrophy of bone and soft tissue always occurs when a nerve is completely severed, but it is significant that neuropathic joints following pressure on the sciatic nerve by bone tumors have been reported. Wile and Butler¹⁰ write of a patient who developed a typical neurotrophic joint following acute arthritis, no serologic or neurologic changes accounting for the condition were found. Shands⁶ reports a neuropathic ankle which occurred several years after an injury to the lower leg, on dissection the distal portion of the posterior tibial nerve was found to be surrounded by cicatricial tissue. He concludes that the scar formation in some manner blocked the sensory fibers leading to the joint but left the motor branches unaffected. Bennett and Hinricson¹¹ note a case of a neurotrophic ankle from the joint fluid of which tubercle bacilli were isolated. They state that the sensory nerve endings must have been adversely affected, and that this left the joint structures without adequate protection. Cases following alcoholic neuritis have been reported, and others secondary to injuries to the posterior nerve roots. Duncan¹² records a painless swelling of a lumberman's wrist which appeared soon after his shoulder had been injured by a falling log. This patient also had sensory changes through his entire arm and shoulder, which indicated that the posterior roots or even the cord had been injured. Another common etiologic factor is trauma at or near the affected joint.

Cotton¹³ tells of seeing several cases of so-called traumatic arthritis accompanied by swelling, and with slight to moderate pain, which upon arthroto-my revealed a joint cavity filled with detritus. This condition is in his opinion closely related to osteochondritis dissecans, but the histology and the macroscopic appearance of the loose bodies and the evident destructive and reparative processes in the joint indicate rather a neurotrophic condition. He states that after removal of the joint debris the pa-

fied by any notation of fluid in the abdomen or chest. In 1913 Titus,⁴ of Boston, in discussing fibroma of the ovary, stated that ascites was an accompaniment in about half the cases. The following year Fullerton⁵ discussed fibroid tumors of the ovary and commented on the frequent early occurrence of ascites. Hellman⁶ in 1915 reviewed the literature and found abdominal ascites in at least 5 per cent of all cases of ovarian fibroma, distinctly less than Titus's 50 per cent. Hellman presented 2 cases of his own which showed ascites. Reel⁷ in 1917 reported ascites in the presence of ovarian fibromas, Saint,⁸ of Edinburgh, in 1919 also found ascites in the presence of a single ovarian fibroid. Richardson,⁹ of London, presented a pathologic specimen of fibroma of the ovary which had been accompanied by ascites. In 1920 Clark and Gabe¹⁰ reviewed the literature and noted the work of Coe in 1882 and of Hellman in 1915. They placed considerable diagnostic value on the presence of fluid in the abdominal cavity. In 1922 Macdonald¹¹ reported ascites accompanying ovarian fibromas.

Not until 1923 do we find any mention made of pleural effusion in the presence of ovarian fibroma. Owen¹² asserted that hydrothorax might occur with ascites. Hoon,¹³ reporting from the Mayo Clinic reviewed all their cases of ovarian fibroma from 1910 to 1921. Out of a total of 4175 tumors of the ovary, he found 55 cases in which the mass was removed at operation and which showed no other pathologic condition. There were in addition 94 fibromas associated with other lesions. Hoon ventured the surmise that the ascites present might be due to peritoneal irritation. Two of his patients also had bilateral hydrothorax, which disappeared after operation. No mention of pleural effusion was made by Likes¹⁴ in 1935.

In the majority of textbooks ovarian fibromas are either ignored or mentioned only in passing. In Crossen's¹⁵ *Diseases of Women* the author devotes only five lines to ovarian fibromas. He states that all solid tumors of the ovary are rare and comprise only about 5 per cent of all ovarian growths coming to operation. In the second edition of Curtis's¹⁶ textbook, discussion of these tumors occupies but seven lines. This author states "Less than 200 cases are recorded in the literature, but inquiry indicates that this is not a true index of their frequency." In Davis's¹⁷ *Gynecology and Obstetrics*, one fourth of a page is given to fibromas along with fibromyomas and myomas of the ovary, and all are classified as relatively uncommon growths. Meigs,¹⁸ in his excellent book *Tumors of the Female Pelvic Organs*, devotes four pages to this particular tumor.

Much credit is due to Meigs and Cass¹⁹ for

emphasizing the syndrome of ovarian fibroma, ascites and pleural effusion, for although it has been recognized that ascites exists very frequently with fibromas of the ovaries, only very recently has the presence of hydrothorax accompanying these tumors been detected. In 1936 they reported a series of 7 cases of fibroma of a single ovary with fluid in the abdomen and in the chest. Four of these were from the Massachusetts General Hospital, 2 from the Mayo Clinic and 1 from the literature.

In all these cases the surgical removal of the fibroma proved to be the only step necessary to relieve the patients of ascites and pleural effusion. The reason for the fluid was neither known nor explained, nor was it at all clear why the removal of the tumor cured the condition. One ovary, never both, was involved, and the right chest was more often involved than was the left. Guinea-pig inoculations with the chest fluid were negative for tuberculosis, and cardiorenal disease was absent. Simple removal of the tumor produced a cure. Thoracic and abdominal paracenteses did not relieve the condition in the least. The entity was found to progress rapidly up to the time of operation.

We wish to report 2 cases, one a unilateral fibroma, the other bilateral and containing a papillary cyst in one ovary, in addition to the fibroma.

Case 1 • E. B., aged 50, a white, married female, was admitted to the gynecological service of the Hartford Hospital on September 15, 1936, complaining of progressive enlargement of the abdomen of 6 weeks' duration, and of difficulty in voiding for a relatively short time. During the previous 6 weeks she had experienced lower abdominal pain, characterized as a heavy, dragging sensation. The former history was unimportant. Menopause occurred 10 years prior to admission, and since then there had been no bleeding.

The positive findings on physical examination were a general appearance of illness, two lipomas on the back, signs of fluid in the right posterior chest, slight enlargement of the heart to the left, an elevated pulse rate, and a pelvic mass rising to the umbilicus, which gave the findings compatible with encapsulated fluid. Roentgen examination of the chest was reported as follows: "Stereoscopic and lateral examination of the thorax shows a moderately large amount of fluid in the right pleural cavity, extending into the interlobar fissures and apparently encapsulated in the axilla. The possibility of an underlying pathologic change in the right pulmonary field cannot be excluded without further examination made after a thoracotomy." The left lung is negative in appearance.

An operation was performed under spinal anesthesia 3 days after admission. A lower midline incision was made. The abdomen was filled with blood-tinged fluid. A solid right ovarian tumor, with loops of bowel adherent to the tumor mass, was visualized. The liver was smooth, and normal to palpation. The gall bladder was negative.

Reported through the kindness of Dr. G. E. Howe, on whose service at the Hartford Hospital the case occurred.

SUMMARY

1 A case of a typical neuropathic ankle joint, without demonstrable serologic or neurologic changes except partial insensibility of local deep tissues, is presented

2 Such painless swelling following trauma is indicative but not pathognomonic of a neuroarthropathy

3 The condition was caused by an unknown neural lesion, probably peripheral and perhaps traumatic in origin

4 The joint lesion resulted from repeated trauma to an insensitive unprotected joint

5 Prognosis is uncertain until the primary cause is found

6 The differential diagnosis of this presumably neuropathic joint condition and similar joint changes caused by known neuropathy is discussed

FIBROMA OF THE OVARY WITH ASCITES AND PLEURAL EFFUSION

STANLEY B WELD, M.D.*

HARTFORD, CONNECTICUT

INTEREST in ovarian tumors has increased during recent years, and has necessitated a reclassification of ovarian embryology and pathology according to modern concepts. We should no longer speak of cancer of the ovary or sarcoma of the ovary, but must differentiate the type of carcinoma by its predominating cell structure and embryologic anlage. Primary tumors of the ovary are not uncommon and may be varied. This must be self-evident to anyone who reviews the complex structure of the ovary—an epithelial covering, the so called germinal layer, a tunica albuginea, a thickened connective-tissue coat beneath the epithelium, a cortex containing the primordial follicles, a medulla containing a few tubular rests from the developmental anlagen and a connective tissue stroma reaching from the cortex to the hilum and attached to the mesentery or mesovarium. In addition, there are numerous and tortuous blood vessels, lymphatics extending from cortex to hilum through medulla, and nerves accompanying the ovarian artery. With this renewed interest in ovarian tumors there have been discovered in the body other pathologic conditions existing simultaneously with these tumors and apparently caused by them.

We are particularly interested in a definite syndrome ovarian tumor, with ascites and pleural effusion. To those unfamiliar with this combination it means malignancy. In Kelly's¹ Gynecology one finds this statement: "Fibroma is among the rarest of pelvic tumors, and is characterized by an indefinite multiplication of all the connective tissue elements of the ovary at the expense of the other histological components. The mass thus becomes a fibroid ovary which may further contain degeneration cysts, dilated blood spaces, and lymph spaces." In the first 10,000 gynecological admissions to the Johns Hopkins Hospital he recorded 10 cases with large fibroid ovaries and 3 with small calcified tumors, an incidence of 0.13 per cent. Ascites was frequently present.

Reviewing the English and American literature we find that ovarian fibromas comprise a small percentage of all ovarian tumors, ranging in different clinics from less than 1 to 4 per cent, and probably averaging 2 per cent. There are several reported cases where abdominal ascites was noted. Boldt² in 1910 reported a case of fibroid tumor of the ovary with ascites. In 1909 Mapes³ reported a similar case, and presented a review of the literature as far back as 1840, in this review he found 71 cases of fibroma not qual-

Presented before the New England Obstetrical and Gynecological Society, Hartford, Connecticut, April 28, 1937.

Assistant in gynecology and obstetrics, Hartford Hospital.

in any part of the peritoneal cavity, nor was there any evidence of extension of the tumor masses to the bowel. There were no bowel adhesions. Each tumor apparently arose from an ovary (Fig 2). Grossly the tumors appeared smooth and nodular, on section they were com-

positioned in the chest taken November 30, 3 months after operation, showed no evidence of pleural effusion (Fig 4).

SUMMARY AND CONCLUSIONS

There is a definite syndrome of ovarian fibroma, ascites and pleural effusion which has only very recently been recognized. Two such cases are described. The cause of the fluid and the reason why removal of the ovarian tumor effects a cure remain unexplained. Many of these cases may be found on medical wards. Internists considering causes of chest fluid and ascites should be aware of the condition, as should surgeons and gynecologists considering the possibility of a malignant tumor with metastases to the chest. Usually but one ovary is involved, but both may be, as noted in a case reported herewith. The cure is surgical removal of the tumor. Irradiation therapy is unnecessary.

posed of dense gray strands of fibrous tissue. Microscopic sections of the solid tumors showed typical fibromas, no anaplasia and no malignancy (Fig 3). In one or two areas the pathologist reported the cells to be somewhat large and slightly hyperplastic. The cyst was lined by low epithelium, which in focal areas was thrown into a papillary arrangement. Here again there was no evidence of malignancy.

The patient had an uneventful convalescence and left the hospital on the 17th postoperative day. X-ray exam-

There was no sign of malignant metastases. The uterus, left tube and ovary appeared normal. Only the tumor was removed.

The pathological report (Dr. Kendall) was as follows: 'Gross: Nodular mass 15 by 12 by 11 cm., encapsulated. On section, it is composed of interlacing strands of rather soft fibrous tissue, through which there are extensive interstitial hemorrhages and dilated vessels. Over one surface is what appears to be a vessel containing blood clot. At one pole of the nodule there is a cyst 3 cm. in diameter, having a ragged, seminecrotic lining. Microscopic: Multiple sections through the nodule show a rather cellular fibrous-tissue proliferation. There are some mitotic figures, a few are not entirely regular. There are extensive areas of myxomatous degeneration, and large vascular spaces are scattered through the tissue, in some of which thrombi are present. Structure is fairly characteristic of a benign fibroma of ovarian stroma. Diagnosis: Fibroma of ovary.'

The patient was discharged on the 19th postoperative day, after an uneventful convalescence. An x-ray of the chest at that time showed less fluid than prior to operation. An x-ray of the chest 7 months after operation showed no evidence of effusion.

Case 2. I. U., aged 55, a white female, was admitted to the gynecological service of the Municipal Hospital, Hartford, on August 21, 1936, complaining of swelling of the abdomen. About 2 months prior to admission she

Figure 1 Roentgenogram of chest before operation, showing pleural effusion

first noticed the swelling. She also complained of pain in both kidney regions and a low sacral backache. There was a history of chronic constipation. The menopause had occurred at 35. The past history was unimportant, except for hospitalizations for glaucoma of the eye and for strangulated hernia. Examination revealed bilateral cataracts, a few coarse rales at the right lung base, with diminished breath sounds over the same area, a blood pressure of 112/68, the abdomen shiny and taut with presence of a fluid wave and a right inguinal hernia in addition to the old herniorrhaphy scar in the same region. Vaginal examination showed a large, hard, irregular mass filling the pelvis, reaching to 2 fingers below the umbilicus, im-

movable, with tenderness in the region of the sigmoid and rectum. The mass filled the posterior cul-de-sac.

X-ray of the chest the day after operation showed no evidence of tuberculosis, but there was increased density at the outer and lower portions of the right lower lobe, with irregularities of the diaphragm and partial obliteration of the costophrenic angle, all indicative of pleural exudate (Fig. 1). The blood Wassermann and Kahn tests

Figure 2 Fibromyomas of both ovaries, papillary cyst of ovary

gave a 2+ reaction. The blood nonprotein nitrogen was 35.9 mg. per cent. The red blood-cell count was 4,030,000 with 85 per cent hemoglobin.

At operation about 3500 cc. of straw-colored fluid was removed from the peritoneal cavity by suction. A solid ovarian tumor 9 cm. in diameter, together with a multilocular cyst, was removed. The lower pelvis was then found to be filled with another ovarian tumor, so situated as to give rise to sigmoidal and rectal obstruction, it was

Figure 3 Photomicrograph of ovarian fibroma

delivered from the pelvis with some difficulty and was removed. Both tubes and the uterus down to the cervix were then removed by the usual procedure followed by a supracervical hysterectomy. No lymph nodes were found

anotic man propped up in bed, in obvious distress. There were moderate dulness and moist rales at both lung bases. The heart was essentially the same as on previous examination, and the blood pressure was 140 systolic, 80 diastolic. The abdomen was distended with fluid, liver and splenic dulness were increased, and there was marked edema of the legs, sacrum, scrotum and hands.

The temperature was 99.4°F, the pulse 84. The respirations were 36.

The urine contained a trace of albumin. The white-cell count of the blood was 11,000. The blood nonprotein nitrogen was 37 mg, and the protein 4.9 gm per cent.

An electrocardiogram taken on the fifth day showed a rate of 133 with sinoauricular tachycardia, depressed S-T₁ and S-T₂ intervals, inverted T₁, low diphasic T₂, practically flat T₃ and flat T₄. Q₃ was present, Q₄ short. The P waves were poorly marked, and S₁ was prominent. The QRS complexes were slightly slurred, and there was slight right-axis deviation.

In spite of digitalis, ammonium chloride and salyrgan therapy he failed to show any improvement. He died on the sixth day.

DIFFERENTIAL DIAGNOSIS

DR JAMES H. MEANS: This is a rather unusual story of rapidly decreasing cardiac reserve over an eighteen-year period in a man who was seventy-one years of age at the time he came under observation. We observe these symptoms of increasing dyspnea related to effort and the gradual development of orthopnea. We note edema which is clearly present at first only when he is upright, disappearing at night, and finally we are told of the development of a considerable degree of generalized cardiac edema which persists and gradually ascends his legs. It seems to me that the edema in the early part of this story is rather more than one would expect solely on the basis of cardiac insufficiency. We know he had some ulcers on the lower legs and are therefore inclined to think there was another factor, namely varicose veins, with secondary varicose ulcers. The cardiac patient with varicosities will get edema more quickly than one who has no varicosities. I am impressed with the story of repeated attacks of bronchitis. He has them over and over again. We learn that he has paroxysms of coughing, possibly fever, and finally we are told that he has attacks which resemble asthma, so we are justified under the circumstances in supposing they are so-called cardiac asthma, and a manifestation of heart failure. On the historical data alone one would be entitled to say that he has cardiac failure which involves both sides of the heart.

When we come to the physical examination, we are told that he is well developed — indeed we are told that he has gained 26 lb, bringing his weight up to 220, so he was an obese subject anyway. We do not know the cause for this gain in weight. It may have been dropsy, but it occurred at a time when he was still able to get about. It is unusual for a man to gain 26 lb from dropsy and still be able to continue with work, but it is possible.

Here is a man then with a large heart, with a systolic but no diastolic murmur. He is described as being short of breath and having cyanosis. No mention is made of the size of the liver, and there is nothing about dilated veins in his neck, so we may assume that the liver is not enlarged and that the veins are not dilated. He apparently has a right hydrothorax and some edema in his left lung.

He is afebrile, from the urinary and blood findings there is no evidence of any disease. He has no azotemia. The protein of the blood is within normal limits. The sedimentation rate is a little high. All I can get out of the electrocardiogram is right axis deviation. For further interpretation I shall be obliged to depend on the cardiologist. Perhaps someone will speak about that later.

I might say that the laboratory and physical findings check with the history and indicate that this man is suffering from some kind of heart disease, with congestive failure and consequent anasarca. His response to digitalis is further evidence that he has congestive heart failure. It is interesting that the pulse rate is the same on his second entry as on the previous entry. Although we do not know whether he was digitalized on the first entry, we assume that he was not. This time he is, but the pulse rate is identical. The respirations are more rapid than previously.

No mention is made of x-ray studies.

DR TRACY B. MALLORY: None were made.

DR MEANS: Might I have the help of the cardiologist on the electrocardiograms if he does not tell me the diagnosis?

DR MALLORY: I think that would be in order.

DR EDWARD BLAND: The first electrocardiogram is consistent with a man of his age, except the right-axis deviation. The T waves are suggestive of a digitalis effect. We do not know whether he was getting it at the time of the first entry. The second electrocardiogram showed a rapid rate, depressed ST₁ and ST₂ and probably represents a digitalis effect. A flat T₄ also suggests digitalis. Here again he had slight right-axis deviation without definite intraventricular block. That suggests a little more than the normal findings in a man of seventy-one.

DR MEANS: It seems obvious that he died of congestive heart failure. The only question is, What kind did he have? The way to approach

TRACY B. MALLORY, M.D., *Editor*

CASE 24061

PRESENTATION OF CASE

First Admission A seventy-one-year-old, white toolmaker entered the hospital with the complaint of gradually increasing dyspnea of eighteen years' duration.

About twenty-five years before entry he had an attack of bronchitis followed by "blood poisoning" in his hand which remained localized. Shortly after that he noticed occasional swelling of his ankles, especially when he stood for a long time. Eighteen years before entry he began to notice dyspnea on exertion and more frequent swelling of his ankles. The swelling always disappeared during the night. During the next thirteen years the symptoms gradually became more marked, and he had recurring head colds and attacks of bronchitis. About five years before entry he began to use two pillows at night. He became dyspneic on moderate exertion, and his ankles were swollen every night. Two years before entry he slowly gained about 26 lb until his weight reached 220. He said that there was no increase in his appetite or change in his eating habits. One year before entry he had a severe attack of bronchitis, and for the first time it was necessary for him to stop work. At that time the edema of his legs had become quite marked, and he developed ulcerations of his lower legs. He remained at home for seven weeks, and then returned to work. His dyspnea had become so marked that he had considerable trouble climbing one flight of stairs, and he had an almost continuous cough, productive of small amounts of mucoid sputum. Six months before entry he noticed edema of his scrotum and slight swelling of his abdomen. Two months later he had another attack of bronchitis with paroxysms of coughing and questionable fever. He stayed in bed for two weeks because of weakness, and after that was unable to return to work. His physician gave him digitalis, which failed to bring about much improvement. During the four months before entry he had nightly attacks of "asthma" which lasted for about half an hour and subsided spontaneously. On several occasions it was necessary for him to spend the night in a chair in order to get any sleep.

One sister died of "dropsy" and one had "dropsy" at the time the patient entered the hospital. His family history was otherwise negative, and his past history was noncontributory.

Physical examination revealed a well-developed man breathing rapidly, with cyanosis of his lips and nailbeds. The lungs showed dullness to flatness at the right base with absent breath sounds, voice sounds and tactile fremitus, and a few fine moist rales at the left base. The heart showed general enlargement with the left border of dullness 13 cm from the midline. The sounds were of poor quality, and A_2 was equal to P_2 . There was a loud systolic murmur at the apex, transmitted to the sternum and axilla. The blood pressure was 140 systolic, 80 diastolic. There was obvious fluid in the abdominal cavity. The subcutaneous tissue of the abdomen, genitalia and legs was edematous.

The temperature was 98.6°F, the pulse 80. The respirations were 25.

The urine had a specific gravity of 1.025 and contained rare hyaline and granular casts. The blood showed a red-cell count of 5,250,000 with 80 per cent hemoglobin, and a white-cell count of 7600, 59 per cent polymorphonuclears. The stool examination was negative. The blood Hinton test was negative. The nonprotein nitrogen of the blood was 28 mg, and the protein 5.9 gm per cent. The sedimentation rate was 0.52 mm per minute.

An electrocardiogram showed a normal rhythm, inverted T_1 and T_2 , low and upright T_3 , and upright T_4 . Q_4 was present, S_1 prominent. The S-T intervals in Leads 1 and 2 were depressed. There was a slight tendency to low voltage and right-axis deviation.

He was treated with large doses of digitalis and with salyrgan, and in three weeks all evidence of cardiac decompensation had disappeared. There was still moderate edema of the legs, particularly on the left, but this was thought to be due to varicose veins or an old phlebitis. He was discharged on the thirty-second day on a digitalis and theobromine regime with Bender bandages for his legs.

Final Admission (six weeks later) After discharge he continued to be dyspneic even on slight exertion, and soon noticed that in spite of exercises, bandages and elevation of his legs the edema began to reappear. His physician took him off digitalis and gave him another medicine which he said contained digitalis. During the two weeks before re-entry he became very orthopneic, the edema spread up to his hips, and he felt very weak and tired.

Physical examination revealed a dyspneic, cy

thing or failed to appreciate the significance of some fact given in this record—we usually do that. There are various fantastic diagnoses that one could indulge in. Dr Mallory once produced a tumor of the heart that gave congestive failure, but I will not enter into any such speculation as that.

DR. MALLORY I should like to raise the question of senile calcified aortic stenosis.

DR. MEANS I suppose I should have thought of that, but there is no mention of a murmur that in the slightest degree suggests aortic stenosis. I cannot make a diagnosis of aortic stenosis without a basal systolic murmur and thrill.

DR. MALLORY He had a systolic murmur.

DR. MEANS It was at the apex and transmitted to the axilla.

DR. MALLORY I mentioned that merely because of all the valvular heart disease we see in this hospital that is the one most frequently missed.

DR. MEANS Is that what he had?

DR. MALLORY No.

DR. JOHN H. TALBOTT I should like to ask a cardiologist if it is possible for a congenital pulmonary stenosis to be asymptomatic until the man was well along in years.

DR. MEANS I did not mention congenital lesions. Dr. White had one patient who died of congenital heart disease at an advanced age but he was not so old as this patient.

DR. MALLORY He was fifty-five, but had had symptoms for many years.

CLINICAL DIAGNOSES

Arteriosclerotic heart disease with congestive failure
Pulmonary infarct?
Anasarca
Varicose veins

DR. MEANS'S DIAGNOSES

Pulmonary heart disease (cor pulmonale)
Multiple pulmonary thrombosis
Congestive heart failure
General anasarca
Varicose veins
Phlebitis with resulting pulmonary embolism?

ANATOMICAL DIAGNOSES

Embolism and thrombosis, old and fresh, of many pulmonary-artery branches
Pulmonary infarcts, recent
Cor pulmonale
Anasarca
Pulmonary tuberculosis, bilateral, healed
Arteriosclerosis marked, abdominal aorta, iliac and popliteal arteries, moderate, coronary arteries

Thrombophlebitis old, popliteal veins, recent, inferior vena cava

Benign hypertrophy of prostate

Duodenal ulcer

Diverticula of colon

Rectal polyp

PATHOLOGICAL DISCUSSION

DR. MALLORY I thought it would be interesting to give Dr. Means a test and see if he remembered the case on which he based a paper about ten years ago. This is the most similar case that we have had since. He has presented it so skilfully that he has made it seem easy and obvious, but I should like to call your attention to the fact that cor pulmonale was not even mentioned as a possibility during either of this man's two sojourns in the hospital. This man, instead of having a single huge thrombus obstructing the main pulmonary artery to one lung, had multiple old organized thrombi in the smaller subdivisions of the arterial tree. One of the major branches to the right upper lobe, the major branch to the right lower lobe and the main branch to the left lower lobe were all occluded by old organized and partially recanalized thrombi. In this case there was no compensatory dilatation of the bronchial artery that we made out in gross. There probably was some that could have been demonstrated if anyone had guessed the diagnosis before autopsy as accurately as Dr. Means has and had injected the lungs with proper technic. In this case I do not believe it would have been very great, however, because there was fairly extensive recanalization of most of the thrombi, and a very marked dilatation at the vasa vasorum which anastomosed extensively with the canalizing vessels. In one of the large canalizing vessels within one of the biggest of the old thrombi, we found a fresh thrombus, which I think may be correlated with the acute episode just before he came in the last time. We also found a number of small recent infarcts way out in peripheral portions of the lung. His popliteal veins showed an occlusive process of an age at least equal to that of the older pulmonary lesions. Both had obviously been at one time completely occluded and had become fairly extensively recanalized. In the inferior vena cava we found a fresh thrombus which was probably the source of the final pulmonary emboli. The lungs, except for the vascular change, were in remarkably good condition. There was no evidence of bronchitis or of emphysema. There was some atelectasis as the result of the bilateral pleural effusions and the apices showed old tuberculous scars.

He had a variety of other conditions, none of them apparently of any clinical importance, such

such a question is to consider all the kinds he could have had, and by elimination, see if one can arrive at a correct diagnosis. Did he have rheumatic heart disease? I suppose it is possible. I have a patient, a man of his age, who has rheumatic mitral stenosis, so one can live that long with mitral heart disease. By some remote possibility he might present a picture like this one, but it is extremely unlikely. There is nothing in the previous story to suggest that he had had heart disease prior to this eighteen-year story. The whole course seems unlikely for rheumatic heart disease. The physical findings of a systolic murmur and a heart transversely widened would be consistent with organic mitral regurgitation, but we have no evidence of stenosis, and altogether the picture does not closely resemble rheumatic heart disease. Syphilis, so far as I know, does not run this long. He is too old for it and certainly has had symptoms too long for syphilitic heart disease. As he also had a negative Hinton test, I shall rule out syphilis, although we must recognize that a few patients with negative serologic tests do have syphilitic heart disease. There is no evidence of hypertensive heart disease, and no evidence in the history, physical examination or electrocardiogram that there is anything whatever wrong with his coronary arteries. There is no evidence of myxedema or thyrotoxicosis.

So by exclusion we are almost led to believe that his heart disease must be secondary to some lesion in the lesser circulation and that this is indeed a case of cor pulmonale. It seems to me that this is suggested by several things. In the first place, cyanosis is mentioned, and cyanosis is more striking in older people with pulmonary heart disease, as I have seen them, than it is in people with other types. It is also suggested by right-axis deviation, although we must concede that organic mitral disease may give a similar picture under certain circumstances. Nothing is said in the physical examination about emphysema, but I am very much impressed with this story of repeated episodes of what is called "bronchitis." It seems to me that coincident with this long history of very gradually progressive heart failure something has been going on in the lungs that was called bronchitis and it may have been associated with a certain degree of gradually increasing pulmonary emphysema. The attacks which he had had were called "asthma," and they would fit into such a conception, although of course they might also have been due simply to acute pulmonary edema as a result of left ventricular failure. I do not believe it is possible to say which they were without having the opportunity to observe them.

I do not believe that he has Ayerza's disease, — he

is far too old, — but there are other things that could go wrong with the pulmonary circuit.

I am reminded very much of a case that I had in the Phillips House a number of years ago that Dr. Mallory did an autopsy on and that we reported together. The man was not so old as this one. He came in with heart failure. We never could figure out why he had so much cyanosis. There was a considerable degree, with nothing apparent in the lungs to explain it. It turned out at autopsy that he had a complete thrombotic occlusion of one pulmonary artery with a collateral circulation through the bronchial artery, which was as big as my little finger. It was a chronic closure of one pulmonary artery, and the compensatory circulation had taken care of the nutrition of the lung. The lung was therefore all right, indeed it was in better shape than the lung that was not shut off from the pulmonary artery because the latter had edema while the former did not. Air went in and out, so that it gave normal physical signs. That case taught me that when you have a cyanosis that seems to be a little difficult to explain you should think of some process in the pulmonary circuit, possibly a thrombosis or perhaps an embolic process. I think Dr. Mallory has taught us of late years that multiple infarcts in the lungs are not at all uncommon. We find over and over again that people have showers of small infarcts in the lungs, and something of that kind may have taken place in this case, so that one might have a combination of simple cardiac failure and some such process in the lungs aggravating the condition. I wonder if the episode that occurred just before the second entry, when he became orthopneic and had rapid spread of edema, might not have been due to something of that sort. I can only guess at that because I have none of the actual criteria to make such a diagnosis. I have no story of bloody sputum — nothing that is definite proof — no story or description of engorged neck veins. I suspect, however, that multiple pulmonary infarction is a good possibility.

The best I can do with this case is to say that the man did have congestive heart failure with a large heart. I should expect to find both sides hypertrophied and dilated, and to find edema of the lungs, hydrothorax and ascites. We know he had all these things. I suspect that some thing will be found in the pulmonary artery in the shape of thrombosis with multiple infarcts. I am intrigued with the story about the veins in the legs and wonder if the situation is a composite one of congestive heart failure due to chronic pulmonary disease and on top of that a phlebitis related to the varicosities in the leg that may provide a source for emboli. That is all I can do with the data I have. I suppose I have forgotten some

was not accompanied by cough or other symptoms. By that time the pain had become very severe and had spread to the left side, deep in the upper quadrant.

Physical examination revealed an extremely obese, acutely ill woman lying listlessly in bed. The skin was sallow. There was marked tenderness in the mid-epigastrium, becoming less acute laterally along the costal margins. A smooth, firm, movable, non-tender mass with rounded edges and smooth surfaces was palpable in the left flank and extended almost into the pelvis. The heart and lungs were negative except for the systolic murmur previously noted. The blood pressure was 100 systolic, 70 diastolic.

The temperature was 99.5°F., the pulse 110. The respirations were 30.

The urine examination was negative. The blood showed a red-cell count of 3,570,000 with 70 per cent hemoglobin. The white-cell count was 10,200, 57 per cent polymorphonuclears and no abnormal forms in the smear. The nonprotein nitrogen of the blood was 59 mg per cent, the protein 4.2 gm. The van den Bergh was normal, indirect. A blood Wassermann test was negative.

An x-ray of the chest showed the right diaphragm to be high and flattened. There were several dense areas just above the right diaphragm which appeared to be areas of atelectasis. The upper portion of the right lung and the entire left lung were clear. A flat plate of the abdomen showed the kidney outlines to be distinct. The left kidney was not quite so low as the right, and there were no stones. A large soft-tissue mass was present in the left upper quadrant which extended down to the region of the crest of the ilium and had the general shape of the spleen. The shadow of the liver did not seem to be grossly enlarged. An intravenous pyelogram showed poor excretion by both kidneys. The pelves and calices were not seen, and the bladder was not filled. A Graham test was done and failed to show any gall-bladder shadow. No gallstones were demonstrated. A barium enema was negative.

On the third day her skin seemed to have a somewhat indefinite, bronzed color and the blood pressure was 82 systolic, 64 diastolic. She was apparently failing rapidly. There were questionable signs of fluid at the right lung base. A consultant reviewed the blood smear and was of the opinion that it showed about 4 per cent very immature white cells. On the seventh day she was very dyspneic, and her extremities were cold, clammy and cyanotic. The nonprotein nitrogen was 130 mg and the carbon-dioxide combining power was 28.8 vol per cent. The serum sodium was equivalent to 110.7 cc., and the serum chloride

to 88 cc of N/10 sodium chloride. She died that day.

DIFFERENTIAL DIAGNOSIS

DR RICHARD B KING It seems to me that the decision we have to make here is whether the first admission had anything to do with her death. I am inclined to believe that she had two unrelated conditions and that the first admission was in some way related to the gall bladder, that is what they were thinking about of course. The description of the attack is perfectly consistent with gall-bladder disease. It lasted two and a half days—a very unusual duration for pain associated with diaphragmatic hernia or acute ulcer. The fact that they mention it was not related to exertion or motion indicates that they thought of coronary thrombosis, but did not believe it was that because they did not have electrocardiograms made. The blood pressure was 150 systolic, 100 diastolic, and examination of the heart itself failed to reveal anything noteworthy. The description of that attack is perfectly consistent with gallstones or cholecystitis, and probably not related to the thing that killed her. It is interesting that she stated that the stools had been black, off and on I presume, for a year. It is always questionable how much importance you can put on such a statement without knowing whether she had taken an iron tonic which would have colored the stools. There was no evidence of trouble in the gastrointestinal tract at the time of first entry. She had a normal gastrointestinal series and a negative barium enema. They were looking for gall-bladder disease, and they did a second Graham test because they were skeptical about the first. We all know, however, that one can have gall-bladder disease without its showing in the Graham test. The shaking chill is curious, I should like to know whether she sweat following it and whether the temperature, which had fallen before the chill, went up again. I do not know how to interpret it. I should guess that at the time of the first admission she had gall-bladder disease, with a long attack of gall-bladder pain.

When we come to the second admission we realize that a lot has happened in the interim, and it is this story which concerns us in regard to the patient's death. The pain in the right upper quadrant, which was constant, unremitting and crushing, is hard for me to believe. I do not see how a patient could live for six months with unremitting, crushing pain, night and day. It seems to me that if it was as severe as described she would have been unable to sleep and would have died of exhaustion. It is impossible for me to relate the pain with the gall bladder, and I do not know any condition in the liver which could cause pain

as a duodenal ulcer, a rectal polyp, diverticula of the colon and a hypertrophied prostate

A PHYSICIAN Did he have any disease of the mitral or aortic valve?

DR MALLORY No He had slightly calcified atheromatous plaques on the posterior surface of the mitral valve, a very common spot for them at that age, and they never, so far as I know, have any functional significance The heart weighed 525 gm The right ventricular wall measured 8 mm in thickness, and the columnae carneae on the right were larger than those on the left The pulmonary orifice was normal in circumference but the tricuspid valve measured 16.5 cm, which indicates considerable dilatation The coronaries showed some calcification but no significant narrowing The liver showed a slight degree of cardiac cirrhosis

DR. MEANS The loud systolic murmur was probably functional

DR MALLORY I should think it must have been

CASE 24062

PRESENTATION OF CASE

First Admission A sixty-year-old Jewish housewife entered the hospital with the complaint of abdominal pain of two and a half days' duration

Two and a half days before entry the patient was quite suddenly taken with a severe pain in the epigastrium which seemed to start on both sides and constrict toward the middle, with radiation through to the back, but not to the shoulders, arms or substernal region The pain was not related to exertion, emotion or the intake of food It was accompanied by nausea, perspiration, hot and cold feelings, some faintness and dizziness, but no vomiting or chills She went to bed, but the pain continued unrelieved by aspirin until the time of entry She was unable to sleep, and in spite of various laxatives failed to have a bowel movement

For the previous three years she had had occasional similar attacks of pain which were very mild and of brief duration During that period she had noticed gradually increasing anorexia so that her diet became very limited, although she still remained very obese Her greatest weight had been 200 lb., and at the time of entry she weighed 180 lb She thought she had lost about 10 lb during the week before entry During the year before entry she had become constipated Previously she had never had any trouble with her bowels, but it became necessary for her to take large doses of laxatives to obtain a movement She stated that her stools had been black during this period but

never bloody or clay colored She had never had any jaundice or other gastrointestinal symptoms.

She had had malaria as a child but denied ever having had typhoid or venereal disease. She experienced some dyspnea on climbing stairs, and she said that her ankles had been swollen for years She had no other cardiorespiratory symptoms For two years she had had some nocturia and frequency The family history was noncontributory

Physical examination revealed an extremely obese woman in considerable discomfort from abdominal pain There was a rough systolic murmur heard all over the precordium, and the heart sounds were of good quality The blood pressure was 150 systolic, 100 diastolic The abdomen showed tenderness to deep palpation in both upper quadrants, more marked on the right just below the costal margin There were no masses or spasm One observer thought the liver edge was palpable There were bilateral varicose veins with varicose ulcers on both lower legs

The temperature was 100.5°F., the pulse 90 The respirations were 20

The urine examination was negative The white-cell count of the blood was 7900 The hemoglobin was 85 per cent The nonprotein nitrogen of the blood was 27 mg per cent, and the van den Bergh was slightly above normal, with an indirect reaction A blood Hinton test was negative.

A Graham test showed normal filling and emptying of the gall bladder, and a gastrointestinal series was negative

She vomited once shortly after entry, and on the second hospital day had a shaking chill, although her temperature had fallen to normal On the ninth day a barium enema showed no evidence of a pathologic lesion, and on the following day the Graham test was again negative The pain subsided during her stay in the hospital, and she was discharged on the eleventh day

Final Admission (eight months later) The patient was fairly well for about two months following discharge, but then began to have severe, constricting pain deep in the right upper quadrant, which did not radiate The pain was constant, unremitting and crushing in nature, not sharp or colicky She had had no known fever or jaundice, and believed that there had been no change in the color of her stools or urine. On one occasion, a short time before re-entry, she had a shaking chill. She developed severe anorexia and, when she did eat, felt nauseated but never actually vomited About a month before re-entry she went to bed because of weakness and continued pain and remained there until she was brought to the hospital Two weeks previously she developed dyspnea which was not relieved by sitting up and

grade of vascular nephritis, not enough, however, in itself to explain uremia. I should be inclined to attribute the renal failure to a combination of factors in a moribund patient. She was hypertensive when she first came in so that she had kidneys accustomed to a blood pressure of 160 systolic, 100 diastolic, and when they were forced to work with a blood pressure of 80 systolic, 60 diastolic, they failed.

A PHYSICIAN: How about the epigastric pain?

DR. MALLORY: I have no explanation for that unless it was due to the spleen, which seems a little unlikely, or to the enormously enlarged retroperitoneal nodes around the celiac axis.

A PHYSICIAN: You did not examine the spine?

DR. MALLORY: We took sections from several vertebrae. We did not examine the cord. It is possible that she had a nerve-root involvement.

of that sort and which would last six months. It might be a nerve pain in the sense that one can have shingles with pain lasting for years, and I should be inclined to interpret it as having something to do with pressure on, or infiltration of, nerves. She was then getting short of breath and in the habit of sitting up. She was probably developing anemia. None of these things suggest trouble in the cardiovascular system. The original swelling of the feet and the shortness of breath which she had had for years could be explained on the basis of the varicose veins and obesity.

The whole crux of this matter seems to rest on whether the mass felt on the physical examination was the spleen. All the evidence points to its being spleen. They did everything to rule out the kidney. It was not a tumor related to the kidney, and a tumor arising from the pelvis would not give that kind of shadow. They made no note of a notch, this is disturbing because in spleens of that size we almost always feel a notch and describe it. I am convinced, however, that the mass was the spleen. Assuming this to be so, we have to explain the anemia, the finding of queer cells in the blood smear, the pain, the patient's death. It seems to me that a lot happened more or less simultaneously in relatively widely separated areas,—the rise in nonprotein nitrogen, the fall in blood pressure, the low serum sodium,—which suggests that we are dealing either with metastases to various places or a widespread vascular disorder, or with what seems more likely to me leukemic infiltration of various organs. As to the cause of death, it could have been renal or adrenal failure, or a combination of the two. The findings in the chest could be leukemic infiltration or irritation of the pleura or lungs, or both. I believe that the patient had gall-bladder disease, not related to death, and aleukemic leukemia type undetermined. There is no description of these peculiar cells which were seen in the blood smear, and the fact that they were not named makes me feel that the observer was unable to classify them.

CLINICAL DISCUSSION

DR J. W. ZELLER. When I saw this patient a few days before death, I thought the mass in the left upper quadrant was the spleen although it was disturbing that it had not been noticed there eight months previously. The lymph nodes were certainly not striking. The inguinal and axillary nodes were not palpable, although at autopsy they looked as if they should have been, in spite of her obesity. The blood smear showed a few young cells, I did not know exactly into what series they fell but thought they were lymphocytes. I thought

she had lymphoblastoma. The systolic murmur was very harsh and certainly indicated some organic disease of the mitral valve.

CLINICAL DIAGNOSES

Coronary thrombosis?
Chronic cholecystitis?
Lymphoblastoma?
Arteriosclerotic heart disease.

DR KING'S DIAGNOSES

Chronic cholecystitis
Aleukemic leukemia, ? type
Leukemic infiltration of kidneys, adrenal glands, spleen, lungs and retroperitoneal lymph nodes

ANATOMICAL DIAGNOSES

Aleukemic lymphatic leukemia
Thrombosis of iliac and pelvic veins and inferior vena cava
Edema of the legs
Hydrothorax, right.
Arteriosclerosis slight, coronary, moderate, aortic, moderate, mitral and aortic valves
Nephritis, chronic vascular
Obesity

PATHOLOGICAL DISCUSSION

DR TRACY B. MALLORY. The autopsy showed a very large spleen that weighed over 1200 gm and a diffuse enlargement of lymph nodes all over the body, particularly the retroperitoneal nodes. The liver was normal in size, but the markings were a little exaggerated—the branchings of the portal tree could be seen with a distinctness that you do not see in a normal liver but do at times in leukemic infiltration. The gall bladder and bile ducts were absolutely negative. The heart showed partially calcified, atheromatous plaques on the mitral valve, the valve margins were normal, and I do not believe its function was interfered with. The one other important finding in gross was a very extensive thrombophlebitis of both iliac veins and of the deep pelvic veins, which had extended up the vena cava as far as the mouth of the renal vein. It was not a completely occluding thrombus, however, filling only about half the lumen. Microscopic examination showed a typical leukemic infiltration of the spleen, lymph nodes, liver and bone marrow. It was of undifferentiated type, but probably lymphoid.

A PHYSICIAN. What about the adrenals?

DR MALLORY. They showed microscopically a little lymphoid infiltration but nothing in gross and nothing that I think could have interfered with function. The kidneys showed a moderate

STATE POSTGRADUATE COURSES

THE plan of the Committee on Postgraduate Education for the present year deserves commendation. Not only is a wide variety of subjects presented to the districts, but there is special emphasis on syphilis and gonorrhea, in collaboration with the program of the United States Public Health Service. "Early Syphilis" and "Gonorrhea in the Male" have been selected for presentation for the present year, with the intent of continuing in future years and eventually covering these subjects thoroughly. It is worthy of note that the course in syphilis has been dedicated to the late Dr. C. Morton Smith, whose interest and advice in the course before his death aided greatly in its preparation.

These courses are illustrated with many lantern slides, including charts and colored slides which show various phases of these diseases. They cover quite thoroughly the practical matters of diagnosis and treatment, and deserve a large attendance by practicing physicians in the various districts. Massachusetts physicians are now given an opportunity to become up-to-date on subjects about which more patients can be expected to ask questions in view of the publicity now being given to these diseases.

CASE HISTORY No 58 BLEEDING AT TERM—
PARTIAL SEPARATION OF THE PLACENTA

Mrs. G. R., a twenty-three-year-old primipara, was admitted to the hospital on October 1, 1937. She was at term, the membranes had ruptured one hour before admission, and she had experienced two or three attacks of mild abdominal pains, and had a slight bloody show.

The family history was negative. The patient's health had always been good. She had had

measles as a child. The onset of menstruation occurred at thirteen. A regular thirty-day cycle was established, and the periods lasted three or four days without pain. The last menstrual period began on December 29, 1936.

The antenatal course was entirely normal. Her blood pressure remained at a level averaging 105 systolic, 70 diastolic. Repeated urinalyses were normal, the blood Wassermann was negative.

She was seen at 5 a. m. on the day of admission. Examination revealed a robust young woman in no apparent distress, with temperature 98.6°F, pulse 80 and respirations 22. The mucous membranes were of normal color. The thyroid gland was slightly enlarged. The lungs were normal to percussion and auscultation. The heart was normal in size, the sounds were regular and clear, no murmurs were heard. Abdominal examination revealed a pregnancy at term. The baby was large and presented as a right occiput anterior. The head was unengaged and could be moved above the pelvic inlet. The fetal heart sounds were normal. Rectal examination revealed a long, thick cervix, which admitted the tip of the examining finger. During the examination a moderate amount of blood-tinged amniotic fluid exuded. Examination of the blood showed a red-cell count of 3,950,000, a white-cell count of 7800 and a hemoglobin of 80 per cent (Sahli), the smear was normal.

Three hours after admission the labor pains were still mild and irregular. The blood loss was definitely in excess of the normal show. The head remained unengaged, and the fetal heart sounds normal. The patient was seen in consultation, and a diagnosis of partial premature separation of the placenta was made. A vaginal examination ruled out a placenta previa. As recommended by the consultant, the cervix and vagina were packed with iodoform gauze, an indwelling catheter was placed in the bladder, and a Spanish windlass was applied. The patient's condition at 11 a. m. was satisfactory, her pulse was strong, and the rate was 96. The blood pressure was 100 systolic, 60 diastolic.

In order to control the restlessness 1/6 gr. morphine sulfate and 9 gr. sodium amylal were given during the early afternoon. At 4 p. m. the patient was not definitely in labor, and 0.07 cc. (1 minim) obstetrical Pituitrin was ordered every half hour for three doses, active labor promptly followed. At 7 p. m. the patient began to complain of pressure on the rectum. The packing was removed, and no bleeding followed. Rectal examination revealed a moderately thick but soft cervix, which was three fingers dilated. The presentation was right occiput transverse, and the vertex was at the level of the ischial spines. During the evening

A series of selected case histories by members of the section will be published weekly.

PROPOSED ADMINISTRATIVE ECONOMIES IN BOSTON

MAYOR TOBIN is to be congratulated on his stand in relation to economy in city administration. As it affects the medical and surgical care of the sick, his first step is, in our opinion, an excellent and long overdue one. The closing of the two relief stations that have for years encumbered the Boston City Hospital is, from the point of view of the individual patient's welfare, a most important and beneficial action. The equipment and personnel at both relief stations has never compared in adequacy with that available at the main hospital and, in the very nature of things, never could. On the other hand, and equally in the very nature of things, this personnel with its inadequate equipment was asked every day and night to face the most difficult and serious types of medical and surgical emergencies — emergencies that, when they

did reach the main hospital, taxed to the utmost that staff with its specialists and modern equipment.

It has been argued that these stations should be kept open. Why? Because, say the proponents, the greater delay necessary to move patients to the main hospital will endanger their lives and welfare. There *was* a significant delay in the horse-drawn ambulance days, but with the modern police or hospital motor ambulance it no longer exists. Is there any other reason why the seriously injured citizens of Boston still must be forced to undergo the most important part of their treatment after a major injury, at the hands of an inadequate staff which is further handicapped by a short age of equipment? Yes. Because these relief stations have served — particularly the East Boston one — as outpatient departments. If they are closed the local residents who need outpatient care will have to go to local physicians or to the Outpatient Department of the main hospital. This is a bother but is no more than that, and does not justify the expenditure of large sums by the city to save patients carfare, nor does it justify subjecting these same patients to an appreciably greater liability to death if and when they are struck by an automobile or fall into the hold of a ship.

This initial move, while most praiseworthy, must not be allowed to justify less meritorious economies. It has been reported in the daily press that the Boston City Hospital budget must be cut \$400,000 in addition. It is hard to see how this can be done without curtailing or even eliminating services that the public has every right to expect and demand. Because these services have not the same news value as that of relief stations does not mean that they are less essential.

The trustees and the Mayor should recognize the futility and danger of forcing the organization at the Boston City Hospital to regress to the conditions of fifteen or twenty years ago. The trustees should not be permitted to do this, nor should the Mayor be allowed, through lack of understanding, to place himself in the position of demanding such a sacrifice even if no money is saved from the hospital budget.

CHILD BEHAVIOR

Since the behavior of children has been a matter of interest to adults from time immemorial, any attempt to deal with what we think we know about the subject must of necessity be very sketchy. Only a few of the high lights, especially those which have been cast by the careful observations of the past few years, can be mentioned.

Children's behavior depends so much upon their physical and mental development that we must consider in our discussion both these factors. Gessell at Yale has pointed out that there are types of activity which usually make up a part of the lives of all normal infants and children at about the same age. Thus the ability to roll over is the foundation stone upon which sitting up is later built, and the ability to understand pictures, peculiar to man and perhaps to the chimpanzee, is the first step toward the understanding and recognition of symbols which make reading possible. There is a growing suspicion that these newly appearing activities are the result of development of parts of the nervous system which are not mature at birth. Thus the normal new born baby does not have to be taught to breathe or suck, if left to itself the need of air will cause it to breathe, and hunger when it comes will cause the baby to suck and swallow when suitable food is properly presented. We call such activities instinctive, but that merely means that the nervous machinery necessary for their carrying out is already present and ready to go at the time of birth. Indeed, as in most of nature's provisions, such leeway is provided that these fundamental activities take place effectively even though birth occurs as much as two months or more before term.

Certain activities which develop after birth are almost as automatic in the normal child as breathing and sucking. Among these may be mentioned sitting, standing and walking. Ordinarily they are not learned in the sense that reading is learned, the growing infant acquires them when he is ready, without teaching or encouragement. Those of us who feel that we must control the world for our children are tempted to try to vary the automatic schedule either by teaching the baby walking before he is ready (to keep him up with the Jones's baby) or by keeping him from walking when he is ready (to prevent his developing bowlegs). Walking develops at about its own pace in either case, and attempts to interfere with it often disturb the baby's disposition.

Many of the other acquired activities of infancy and childhood are largely automatic and the result of ripening processes in the nervous system. If not interfered with by ambitious or solicitous parents, they appear in an orderly fashion, but if attempts are made to force them, resistances and emotion are often built up which delay or modify their appearance. It is impossible to describe all these activities but as examples may be mentioned such things as being weaned from the bottle to the cup, chewing and swallowing solid foods, and the like. Of course, if the baby is never given the cup or solid foods he will not learn to deal with them, but if too much interest and effort are centered on teaching their use too early, resistance to them is often established. Such an attitude of resistance may delay the accomplishment of the desired activity for a long time, and may influence the personality of the child toward his family or the world in later life.

The control of bowel movements and urine is a matter over which many parents fuss too much. All dog trainers know that it is useless to try to housebreak a puppy

before it has attained an age of several months, but parents are often unwilling to wait a reasonable time before attempting so to train their children. Everyone knows that people accustomed to handling babies can prevent their soiling themselves in the day by having them use a chamber from the time they are a few months old, but this is not so much training the baby as it is getting the nurse to learn when a movement may be expected and acting accordingly. It is also possible to keep a toddler dry in the day by having an adult handy to put him on the toilet every fifteen minutes or half hour or however often he needs to go, an interval usually ascertainable by observation. This is not education so far as the baby is concerned and may well rouse antagonism on the baby's part to an extent making it wise to abandon attempts to teach toilet habits at this age. Even after the child has learned to ask to go, it is important to realize that the interval between his warning sensation and the need for relief is so short that it may be impossible for him, in spite of the best intentions, to reach the toilet in time.

Bed wetting is a type of infantile behavior often carried over into childhood, often because of too early enthusiastic efforts to stop it. Dry nights may become habitual as a result of picking up two-year-old children at adult bed time and taking them to the toilet. Many children do not, however, respond to this treatment, and it is most important that their wet beds shall not be considered a matter of interest until they are three years old or more. Realization of these facts would, of course, not prevent all the wet beds in Christendom, but would certainly reduce their number.

The older children become, the more important teaching is in their learning new activities. In spite of this, the fact that growing up is still going on in the brain must never be forgotten. Reading is such an activity. No one would expect most three- or four-year-old children to learn to read, some children are ready to learn at four or five, most by six and an appreciable number, who are otherwise quite normal, not until they are eight or nine. An occasional child will pick up reading from magazines about the house or from his brothers and sisters at home, but for most children reading is an acquired art learned only through the medium of suitable material properly presented. The point I wish to make is that until the child is ready to learn to read, it makes no difference how skillfully the subject is presented to the child he cannot make use of it. Psychologists and schoolteachers have recently been working out tests to show whether a child is ready for reading. If these tests could be applied to all children before any attempt to teach reading is made, and if parents could be persuaded to accept the results placidly, it would cut out many, many hours of heartache and the resultant behavior difficulties.

It is therefore of the utmost importance for parents to realize that their place in the care of their infants and children is in supplying to them food, clothing, shelter and affection. The fact that it is so much more convenient to have food prepared at stated times and that the busy mother or nurse can bathe and dress the child at only certain times, will automatically teach him a little about getting on with the world. Little children will learn most of what they need to learn either automatically or by imitation. If at appropriate ages they have not, then careful investigation of why they do not is in order.

* * *

Q I have a family of several children about whom I should like to ask you. In the first place my baby of twelve months is not yet walking. When I see my neighbor's baby two months younger, walking I wonder

A. Green Lights to Health broadcast given by Dr. Randolph K. Byers on Wednesday January 26 and sponsored by the Public Education Committee of the Massachusetts Medical Society and the Massachusetts Department of Public Health.

she was given 6 gr sodium amytal. Throughout this time there was no vaginal bleeding, and the fetal heart sounds remained normal. At midnight the head was on the perineum. The voluntary effort in the second stage was poor, this was probably due to the medication. Solid blade forceps were applied to the head on the perineum, a median episiotomy was made, and a 9-lb baby boy easily delivered. The infant cried spontaneously. The blood loss during the delivery did not exceed 300 cc, and the total blood loss was approximately 450 cc. The placenta was rectangular in shape. There was an adherent dark-red blood clot covering one angle.

The puerperium was afebrile, and the patient was discharged home on the twelfth postpartum day. The episiotomy was well healed, and the uterus had involuted normally. The baby had regained its birth weight.

Comment. Conservative treatment is of value in cases of premature separation of the placenta if the baby is dead, or very premature, if the mother is very toxic and the chances for a living baby are poor, if the mother is a poor operative risk or if labor has started and examination reveals a soft cervix with some dilatation, and if it is felt that the so-called Couvelaire uterus is not present. The conservative treatment consists of methods to control the bleeding, to improve the patient's general condition and to deliver the baby. The patient should be treated for shock, if it is present. The cervix and vagina should be packed tightly with iodoform gauze or sterile gauze, or a Voorhees's bag should be inserted, and a firm binder with a Spanish windlass should be applied to the abdomen. This usually controls the bleeding. Blood transfusion may then be resorted to, if indicated, or intravenous glucose may be given. Small doses of analgesic drugs should be administered, and when the cervix is fully dilated, the baby should be delivered. This case illustrates the use of conservative treatment.

However, if we have a living baby at term, in a primipara who has a long rigid, undilated cervix, delivery is best accomplished by an abdominal cesarian section. This also applies to patients in whom uteroplacental apoplexy (Couvelaire uterus) is suspected. In some cases of uterine apoplexy it may be necessary to resort to the Porro operation to control the bleeding.

MEDICAL POSTGRADUATE EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public

Health Service and the Federal Children's Bureau, have been arranged for the week beginning February 14

BRISTOL NORTH

Thursday, February 17, at 4 00 p m., at the Morton Hospital, Taunton. Subject: The Use and Misuse of Prontylin. Instructor: Benjamin W Carey, Jr. Arthur R. Crandell, *Chairman*.

BRISTOL SOUTH (New Bedford Section)

Friday, February 18, at 4 00 p m., at St. Luke's Hospital, New Bedford. Subject: The Use and Misuse of Prontylin. Instructor: Benjamin W Carey, Jr. Robert H Goodwin and Howard P Sawyer, *Chairmen*.

ESSEX SOUTH

Tuesday, February 15, at 4 00 p m., in the Nurses Home, Salem Hospital, Salem. Subject: Pneumococcus Pneumonia and Serum Therapy. Instructor: Maxwell Finland. Walter G Shippen, *Chairman*.

MIDDLESEX EAST

Tuesday, February 15, at 4 00 p m., at the Melrose Hospital, Melrose. Subject: Cesarean Section, Analgesia. Instructor: M. Fletcher Eades. Joseph H. Fay, *Chairman*.

MIDDLESEX NORTH

Friday, February 18, at 7 00 p m., at St. John's Hospital, Lowell. Subject: Early Syphilis. Instructor: C Guy Lane. William S Lawler, *Chairman*.

NORFOLK

Friday, February 18, at 8 30 p m., at the Norwood Hospital, Norwood. Subject: Atelectasis in the Newborn. Instructor: Clement A. Smith. Hugo B C Ruemer, *Chairman*.

NORFOLK SOUTH

Monday, February 14, at 8 30 p m., at the Quincy City Hospital, Quincy. Subject: Differential Diagnosis and Treatment of Scarlet Fever. Instructor: Edwin H Place. David L. Belding, *Chairman*.

PLYMOUTH

Tuesday, February 15, at 4 00 p m., in the Rosa Field Nurses' Residence, Brockton Hospital (rear of hospital), Brockton. Subject: Rheumatic Infection, Rheumatic Heart Disease. Instructor: Edward F Bland. Walter H. Pulsifer, *Chairman*.

WORCESTER (Milford Section)

Thursday, February 17, at 8 30 p m., in the Nurses Home of the Milford Hospital, Milford. Subject: Toxemias of Pregnancy. Instructor: John Rock. Joseph Ashkins, *Chairman*.

WORCESTER NORTH

Friday, February 18, at 4 30 p m., at the Burbank Hospital, Fitchburg. Subject: Differential Diagnosis and Treatment of Scarlet Fever. Instructor: Conrad Wesselhoeft. Edward A Adams, *Chairman*.

CHILD BEHAVIOR

Since the behavior of children has been a matter of interest to adults from time immemorial, any attempt to deal with what we think we know about the subject must of necessity be very sketchy. Only a few of the high lights, especially those which have been cast by the careful observations of the past few years, can be mentioned.

Children's behavior depends so much upon their physical and mental development that we must consider in our discussion both these factors. Gessell at Yale has pointed out that there are types of activity which usually make up a part of the lives of all normal infants and children at about the same age. Thus the ability to roll over is the foundation stone upon which sitting up is later built, and the ability to understand pictures, peculiar to man and perhaps to the chimpanzee, is the first step toward the understanding and recognition of symbols which make reading possible. There is a growing suspicion that these newly appearing activities are the result of development of parts of the nervous system which are not mature at birth. Thus the normal new-born baby does not have to be taught to breathe or suck, if left to itself the need of air will cause it to breathe, and hunger when it comes will cause the baby to suck and swallow when suitable food is properly presented. We call such activities *inscune*, but that merely means that the nervous machinery necessary for their carrying out is already present and "ready to go at the time of birth. Indeed, as in most of nature's provisions, such leeway is provided that these fundamental activities take place effectively even though birth occurs as much as two months or more before term.

Certain activities which develop after birth are almost as automatic in the normal child as breathing and sucking. Among these may be mentioned sitting, standing and walking. Ordinarily they are not learned in the sense that reading is learned, the growing infant acquires them when he is ready without teaching or encouragement. Those of us who feel that we must control the world for our children are tempted to try to vary the automatic schedule either by teaching the baby walking before he is ready (to keep him up with the Jones' baby) or by keeping him from walking when he is ready (to prevent his developing bowlegs). Walking develops at about its own pace in either case, and attempts to interfere with it often disturb the baby's disposition.

Many of the other acquired activities of infancy and childhood are largely automatic and the result of ripening processes in the nervous system. If not interfered with by ambitious or solicitous parents, they appear in an orderly fashion, but if attempts are made to force them, resistances and emotion are often built up which delay or modify their appearance. It is impossible to describe all these activities but as examples may be mentioned such things as being weaned from the bottle to the cup, chewing and swallowing solid foods, and the like. Of course, if the baby is never given the cup or solid foods, he will not learn to deal with them, but if too much interest and effort are centered on teaching their use too early, resistance to them is often established. Such an attitude of resistance may delay the accomplishment of the desired activity for a long time, and may influence the personality of the child toward his family or the world in later life.

The control of bowel movements and urine is a matter over which many parents fuss too much. All dog trainers know that it is useless to try to housebreak a puppy

before it has attained an age of several months, but parents are often unwilling to wait a reasonable time before attempting so to train their children. Everyone knows that people accustomed to handling babies can prevent their soiling themselves in the day by having them use a chamber from the time they are a few months old, but this is not so much training the baby as it is getting the nurse to learn when a movement may be expected and acting accordingly. It is also possible to keep a toddler dry in the day by having an adult handy to put him on the toilet every fifteen minutes or half hour or however often he needs to go, an interval usually ascertainable by observation. This is not education so far as the baby is concerned and may well rouse antagonism on the baby's part to an extent making it wise to abandon attempts to teach toilet habits at this age. Even after the child has learned to ask to go, it is important to realize that the interval between his warning sensation and the need for relief is so short that it may be impossible for him, in spite of the best intentions, to reach the toilet in time.

Bed wetting is a type of infantile behavior often carried over into childhood, often because of too early enthusiastic efforts to stop it. Dry nights may become habitual as a result of picking up two-year-old children at adult bed time and taking them to the toilet. Many children do not, however, respond to this treatment, and it is most important that their wet beds shall not be considered a matter of interest until they are three years old or more. Realization of these facts would, of course, not prevent all the wet beds in Christendom, but would certainly reduce their number.

The older children become, the more important teaching is in their learning new activities. In spite of this, the fact that 'growing up' is still going on in the brain must never be forgotten. Reading is such an activity. No one would expect most three or four-year-old children to learn to read, some children are ready to learn at four or five, most by six and an appreciable number, who are otherwise quite normal, not until they are eight or nine. An occasional child will pick up reading from magazines about the house or from his brothers and sisters at home, but for most children reading is an acquired art learned only through the medium of suitable material properly presented. The point I wish to make is that until the child is ready to learn to read, it makes no difference how skillfully the subject is presented to the child, he cannot make use of it. Psychologists and schoolteachers have recently been working out tests to show whether a child is ready for reading. If these tests could be applied to all children before any attempt to teach reading is made, and if parents could be persuaded to accept the results placidly, it would cut out many, many hours of heartache and the resultant behavior difficulties.

It is therefore of the utmost importance for parents to realize that their place in the care of their infants and children is in supplying to them food, clothing, shelter and affection. The fact that it is so much more convenient to have food prepared at stated times and that the busy mother or nurse can bathe and dress the child at only certain times, will automatically teach him a little about getting on with the world. Little children will learn most of what they need to learn either automatically or by imitation. If at appropriate ages they have not, then careful investigation of why they do not is in order.

* * *

Q I have a family of several children about whom I should like to ask you. In the first place my baby of twelve months is not yet walking. When I see my neighbor's baby, two months younger, walking, I wonder

A. Green Lights to Health broadcast given by Dr. Randolph K. Byers on Wednesday January 26 and sponsored by the Public Education Committee of the Massachusetts Medical Society and the Massachusetts Department of Public Health.

whether my baby has spinal trouble or whether his brain is all right. What should I do about it?

A. There is a great difference in the age at which normal babies learn to walk. If the baby seems otherwise active and normally interested in his surroundings, have patience. If you think he is not so active as he should be, take him to your doctor for advice, but do not try to urge him to walk, without advice.

Q. Washing and sterilizing bottles is so much trouble that I have taught this baby to drink from a cup. Lately I notice he is sucking his thumb a lot. What should I do about it?

A. Sucking is to a large extent an important emotional satisfaction to infants, the need for which is outgrown at variable ages. Your baby probably still needs it. If you let him get his satisfaction in the way he was meant to in getting his food, he may be less tempted to get it by sucking his thumb. In any case, thumb-sucking at this age is so common that strenuous attempts to break the habit are unnecessary.

Q. My boy of four is so lazy he will not learn to dress himself. How can I teach him?

A. Many children of four are not yet sufficiently skillful with their fingers to fasten buttons. Get him the sort of underwear held on by soft elastic strips around the shoulders and let him put that on while you fasten the buttons of his outer clothing.

Q. My two-year-old is terrible, whatever I ask of him he says, "No."

A. One of the striking characteristics of many two-year-olds is so-called negativism. Try to warn him that you are going to make a request a few minutes before you make it, and then make it in a quietly confident manner. Be very sure to make just as few requests as possible.

Q. I have tried to train this child to move his bowels every day at the same time, but sometimes he moves them twice one day and not at all the next. How can I train him?

A. Regularity of bowel movement at his age is not essential, though very desirable. If his stools do not become hard, let him move his bowels when he feels the need. Very often the price paid in emotional upset by the baby and parent in securing absolute regularity of bowel movement is not worth the result.

* * *

In summary I want to stress the fact that the development of new activities in babies and young children comes not as the result of teaching but as the result of development and growth in the brain and nerves attached to it. Attempts to interfere with the unfolding of the normal schedule of activity, if carried on strenuously, tend to rouse resistances and dislikes in babies, which very often affect their personalities in childhood and adult life. The temptation to send children to school before their brains have matured to the point which allows them to understand schoolwork is very apt to have the same sort of effect. Mistakes along these lines on the part of parents are very apt to cause unsatisfactory behavior in their children, and tolerance on the part of parents for slow development in the babies is often rewarded by children with stable dispositions.

MISCELLANY

DR. VAUGHAN TO ADDRESS MEETING OF BOSTON TUBERCULOSIS ASSOCIATION

Dr. Henry F. Vaughan, who has been the health commissioner of Detroit, Michigan, since 1919, will be the speaker at the annual meeting of the Boston Tuberculosis Association which will be held at the Hotel Copley Plaza on February 15, at 4 p. m. Dr. Vaughan has been with the Detroit Health Department since 1914, first serving as sanitary engineer and later as assistant health commissioner. During the World War he dropped out of the department to serve as captain in the Sanitary Corps, United States Army. At Camp Upton he was the camp epidemiologist, then, together with Major Russell L. Cecil, he was commissioned by Surgeon General Gorgas to make a special study of the epidemiology and prevention of pneumonia at Camp Wheeler. Dr. Vaughan is a trustee of the W. K. Kellogg Foundation with headquarters in Battle Creek, Michigan. This foundation, chartered to improve the health, welfare and happiness of children, is conducting a community health service program in seven rural counties of southwestern Michigan. An effort is being made to co-ordinate all the resources of these communities for the improvement of child health. The foundation is spending approximately \$1,000,000 annually in this program. Dr. Vaughan has been particularly interested in recent years in advancing the so-called plan of medical participation—the purpose of which is to extend the influence of the community health service by integrating therein the facilities and services of the physician and dentist in private practice. This type of program is proposed as an adjunct to the fundamental services of a whole time local health department. Dr. Vaughan has served on innumerable committees, both administrative and research, of the American Public Health Association, of which organization he was president in 1925. He has also served on the boards of many other national health organizations. He has been a teacher of public health administration since 1915 and is now professor of public health administration at Wayne University, Detroit, and a special lecturer at Vanderbilt University and the University of Michigan.

RÉSUMÉ OF COMMUNICABLE DISEASES IN MASSACHUSETTS FOR DECEMBER, 1932

DISEASES	DECEMBER 1932	DECEMBER 1931	FIVE YEAR AVERAGE
Anterior poliomyelitis	1	0	6
Chickenpox	1671	1393	1484
Diphtheria	18	18	78
Dog bite	574	497	413
Dog bites	72	63	108
German measles	495	590	579
Gonorrhea	411	557	504
Lobar pneumonia	349	2006	1182
Measles	4	12	8
Meningococcus meningitis	298	663	608
Mumps	0	0	0
Paratyphoid A	3	1	0
Paratyphoid B	928	753	956
Scarlet fever	475	444	401
Syphilis	341	203	261
Tuberculosis, pulmonary	43	25	25
Tuberculosis other forms	19	5	10
Typhoid fever	8	3	2
Undulant fever	732	1738	899
Whooping cough			

*Based on figures for preceding five years

RARE DISEASES

Anterior poliomyelitis was reported from Chicopee, 1, *Diphtheria* was reported from Athol, 1, Boston, 1, Brockton, 2, Cambridge, 1, Chelmsford, 2, Chelsea, 1, Fall River, 3, Framingham, 1, Lawrence, 1, Lynn, 1,

Peabody, 1, Southbridge, 2, Tewksbury, 1, total, 18

Dysentery, amebic, was reported from Newton, 1

Dysentery, bacillary, was reported from Boston, 1, Cambridge, 9, Fall River, 4, New Bedford, 3, Revere, 1, Wellesley, 1, total, 19

Encephalitis lethargica was reported from Northampton, 1

Leprosy was reported from New Bedford, 1

Meningococcus meningitis was reported from Melrose, 1, Pittsfield, 1, Rockland, 1, Tyngsboro, 1, total, 4

Paratyphoid B was reported from Boston, 1, Greenfield, 1, Monterey, 1, Revere, 1, total, 4

Pfeiffer bacillus meningitis was reported from Westfield, 1

Septic sore throat was reported from Beverly, 1, Boston, 2, Cambridge, 2, Gardner, 4, Lawrence, 1, Rutland, 1, Somerville, 1, Wellesley, 1, total, 13

Tetanus was reported from Amherst, 1

Trachoma was reported from Everett, 1, Plymouth, 1, total, 2

Trichinosis was reported from Springfield, 1

Typhoid fever was reported from Belmont, 1, Cambridge, 1, Lowell, 1, Medford, 1, Sharon, 1, Somerville, 1, Stoughton, 13, total, 19

Undulant fever was reported from Boxboro, 1, Brookline, 1, Fitchburg, 1, North Adams, 1, Sterling, 1, Taunton, 2, Westfield, 1, total 8

Diphtheria continued to show low incidence.

Measles, mumps, German measles, and scarlet fever were reported below the five year average.

Paratyphoid fever continued to show record high incidence.

The reported incidences of anterior poliomyelitis, meningococcus meningitis, lobar pneumonia and whooping cough were below the five year average.

Undulant fever showed record high incidence.

Pulmonary tuberculosis, chickenpox and tuberculosis (other forms) were reported above the five year average.

The increase in the reported incidence of typhoid fever was associated with a recent outbreak in Stoughton, epidemiological investigation implicated a banquet, the food of which had been prepared by a carrier

Animal rabies showed record low incidence. New foci were reported in Fitchburg and Westborough

CAMBRIDGE MUNICIPAL TUBERCULOSIS HOSPITAL

Plans have been announced whereby the present Cambridge Home for the Aged and Infirm will be converted into a tuberculosis hospital. In order to meet the minimum standards of the Massachusetts Department of Public Health it was estimated that an outlay of nearly \$400,000 would have been required to build and equip an additional wing to the present sanatorium. The plan has been approved by the Commissioner of Public Health, and the former inmates of the home will be cared for in other institutions, nursing homes and private homes.

CONGRESS ON MEDICAL EDUCATION AND LICENSURE

The thirty fourth annual Congress on Medical Education and Licensure will be held at the Palmer House, Chicago, on February 14 and 15. The first day will be devoted to papers and discussions on medical education. Dr Ray L. Wilbur, of Stanford University, will preside at the morning session, and Dr Frederic A. Washburn,

of Boston, in the afternoon. Of the two morning sessions on the second day, one covering postgraduate education will be in charge of Dr Charles G. Heyd, of New York City, while Dr Jesse W. Bowers, of Fort Wayne, Indiana, will preside at a joint meeting of the Council on Medical Education and Hospitals and the Federation of State Medical Boards. The afternoon session of the Federation of State Medical Boards will be a symposium on promulgation of regulations authorized by law, and will be in charge of Dr Bowers.

REVISION OF PHARMACOPOEIA TESTS

The following revision of the U.S.P. XI tests is hereby announced through the authority of the Committee of Revision and the action of the Board of Trustees.

Aqua Auranti Florum Page 64

Change the test for residue on evaporation to 'Evaporate 100 cc. of the Orange Flower Water on a water bath, and dry the residue to constant weight at 100°C. not more than 0.005 gm. of residue remains'

Benzoinum Page 86.

Omit the test for 'rosin, lines 13 and 14 from the bottom of the page.

Oleum Amygdalae Expressum Page 248

Omit the test for the solidification point of the fatty acids, lines 9 and 10 from the bottom of the page.

The urgency of the revision of these three tests, due to their involving the importation of these official items, necessitates an interim revision announcement. It is expected that from time to time other revisions in official texts will be similarly announced, to meet conditions which demand prompt action.

When enough of these interim revision announcements have accumulated and other added or revised monographs have been adopted it is expected that all these new and revised texts, approved since the appearance of the *First U.S.P. XI Supplement* will be reprinted in full and issued as the *Second U.S.P. XI Supplement*. Interim revisions are being announced through the medical and pharmaceutical press.

E. FULLERTON COOK, *Chairman*
Committee of Revision
of the U. S. Pharmacopoeia

MEDICAL ART ASSOCIATION

The American Physicians' Art Association, a national organization of medical men who have ability in the fine arts, will hold a first national exhibition in the San Francisco Museum of Art, San Francisco, California, in June 1938. (The American Medical Association Convention is June 13-17 in the same city.) The American Physicians Art Association already has an outstanding membership. There are three classifications for membership: active, associate and contributing. The first annual exhibition promises to be of unusual interest with entries to be accepted (after jury selection) in the following classifications: oils, watercolors, sculpture, photography, pastels, etchings, crayon and pen and ink drawings (including cartoons), wood carvings and book bindings. Scientific medical art work will not be accepted. The exhibition is not limited to first showings. All entries close April 1, 1938. Any physician interested should communicate at once with the Secretary of the American Physicians Art Association, Suite 521 536 Flood Building, San Francisco, California.

CORRESPONDENCE

MEDICAL RECORDS

To the Editor The question as to what provision a physician or surgeon should make in regard to his medical records is one which I should like to have help in solving. I am writing this letter in hope that some of the readers of the *Journal* will have sufficiently concrete ideas so that a policy may be formed.

The whole subject was recently brought forcibly to my attention when I saw a doctor's heirs offering for sale his files with the records in them. This was in a small town where several prospective purchasers would have been glad to obtain news about the neighbors. Fortunately, this catastrophe was averted, but it made me think how I should protect my own records.

With the growth of scientific medicine and the careful investigations that many doctors give their patients, combined with the detailed histories, x-ray findings, laboratory reports and records of operations, I believe that a certain proportion of our records would be of real value to the doctor who treats these patients from where we leave off. Would it be feasible for a doctor to leave his records to a small group of physicians with a sufficient sum of money to pay for their storage with the understanding that that group would look through a record before giving it out to the physician to whom it might be of help so that personal letters and irrelevant statements could be first deleted? I have personally had patients referred to me, whose previous surgeon had died, where the pathological findings and procedures of a previous operation would have been very helpful. I believe that in straight medical cases the past histories and laboratory findings would be equally useful to a physician who was carrying on.

At present, I can see no course open to us as physicians but the simple one of burdening our nonmedical families with the responsibility of our records and the request that they be destroyed at the end of a certain period of time.

HILBERT F DAY, M.D.

412 Beacon Street,
Boston

ARTICLES ACCEPTED BY THE AMERICAN MEDICAL ASSOCIATION COUNCIL ON PHARMACY AND CHEMISTRY

To the Editor In addition to the articles enumerated in our letter of December 4, the following have been accepted:

Mallinckrodt Chemical Works
Hippuran, 100 gm. bottle
Hippuran, 500 gm. bottle

Sharp & Dohme
Rabies Vaccine (Phenol Killed) (Semple) 14 dose package, with syringe

John Wyeth & Brother, Inc.
Vaginal Suppositories Silver Picrate—Wyeth's, 1 gr (infant size)

PAUL NICHOLAS LEECH, *Secretary*

535 North Dearborn Street,
Chicago, Illinois

MEDICAL SERVICE IN CHINA

To the Editor The Emergency Medical Committee for China of the Foreign Missions Conference of North America has been set up for the purpose of finding a group of

selected young surgeons for service in China to relieve the terrific pressure put on existing medical institutions in caring for war wounded. The need for immediate assistance can hardly be exaggerated, as many thousands of soldiers and civilians are undergoing untold suffering, being still uncared for in every way.

I am taking the liberty to ask your assistance in canvassing for available young men with surgical experience—married or single—who could go out alone for at least one year for such service as above indicated.

This committee is offering expenses paid to and from the Far East, and a salary equal to the average now being paid to medical workers in China.

We shall especially appreciate the recommendation of individuals who you think would be suitable and interested in humanitarian service, and I shall be glad to arrange for personal interviews, either here or elsewhere, with any candidates that you might recommend.

S H LILJESTRAND, M.D.,
Executive Secretary

Room 811, 150 Fifth Avenue,
New York City

RECENT DEATHS

LARSON—CARL G LARSON, M.D., of 119 High Street, Medford, died December 23. He was in his forty third year.

Dr Larson received his degree from the College of Physicians and Surgeons in Boston in 1927.

He was a fellow of the Massachusetts Medical Society and a member of the American Medical Association.

LEARD—JOHN S LEARD, M.D., of West Roxbury, died at his home, February 3, after a week's illness. He was in his seventy second year.

A native of Prince Edward Island, he graduated from Prince of Wales College and received his degree from the University of Pennsylvania School of Medicine in 1894.

Dr Leard was a member of the original staff of the Faulkner Hospital and was organizer and first president of the West Roxbury Roslindale Jamaica Plain Medical Association. He was a fellow of the Massachusetts Medical Society and the American Medical Association. At the time of his death he was vice president of the Jamaica Plain Dispensary and a member of the Clinical Club of Boston and of the Norfolk District Medical Society of which he was a past president, councilor and censor.

Among his other affiliations were memberships in the Masonic Order, the Unitarian Club of West Roxbury, the Emmanuel Men's Club and the Highland Club of West Roxbury.

His widow, a daughter and twin sons survive him.

REPORT OF MEETING

NEW ENGLAND HEART ASSOCIATION

The regular monthly meeting of the New England Heart Association was held at the Peter Bent Brigham Hospital on January 24. The following program was presented:

THE DEVELOPMENT OF FATAL LUETIC AORTITIS WITHIN TWO YEARS AFTER PRIMARY INFECTION. Maurice A. Schnitzer, M.D.

The case was that of a Canadian born housewife, age twenty three, who, except for two operations, was cared for in a distant hospital. Married at sixteen, she went through normal pregnancies at seventeen and at eighteen. In the next three years she was hospitalized for breast abscess, acute gonococcal salpingitis and minor illness, during which time three blood tests for syphilis were negative. Examination of the heart during this period was entirely normal. At the age of twenty-one, one and a half years after the gonococcal infection, she contracted syphilis, being seen in the secondary stage of the disease, with Wassermann, Kahn and Hinton tests positive. She was treated for the next seven months, irregularly, with sulfarsphenamine, this was essentially the only treatment received. Six months after the onset of the syphilis, while under treatment, she began to have typical angina pectoris with radiation of pain to both arms and hands. At that time the heart was enlarged, and revealed coarse, systolic and diastolic murmurs of aortic insufficiency and an Austin Flint sound. Nitroglycerin gave some relief. At twenty two, the pains were incapacitating, and she entered the Peter Bent Brigham Hospital where left cervicothoracic sympathectomy was done with temporary complete relief of pain. At this time physical examination and x-ray showed, in addition, a large aneurysm of the aorta. Electrocardiograms revealed only left-axis deviation. Two months later, with severe recurrence of pain in the right shoulder, arm and back, she re-entered the hospital and a right sympathectomy was performed. Pain recurred several weeks later, with severe dyspnea and hemoptysis. She died in an attack of pain at the age of twenty three, two years after the onset of syphilis and eighteen months after the beginning of cardiac symptoms. At necropsy, the heart weighed 790 gm. and showed a huge aneurysm of the aorta, syphilitic aorta insufficiency and practically complete occlusion of the right coronary ostium.

SOURCES OF ERROR IN THE DIRECT METHOD OF VENOUS PRESSURE. Richard H. Lyons, M.D., J. Allen Kennedy, M.D., and C. Sidney Burwell, M.D. Presented by Dr. Lyons.

There is wide variation in the reports of venous-pressure measurements in normal people. This results from a lack of uniformity of methods used and from variations in the position of the reference point. In an effort to define more closely the normal limits of venous pressure, certain sources of error in the direct method have been considered. The position of the site of venipuncture, the bore of the manometer and variations in the physiologic state of the subject may distort the venous-pressure readings. Venous pressures were determined on 90 normal subjects, and the suitability of the reference points of von Recklinghausen, Moritz and Tabora, and Eyster. It was found that the use of reference points involving the thoracic diameter of the subject gave lower venous-pressure readings in subjects with larger chests. This may be eliminated by using the table top as the reference point with the patient in the supine position.

PHYSIOLOGIC EFFECTS OF ARTIFICIAL FEVER. John G. Gibson, 2nd, M.D.

The physiologic effects of artificial fever can be interpreted in light of the great increase over normal in heat exchange. Extreme vasodilatation occurs in the effort to maintain normal temperature, with increase in pulse rate, blood flow, venous pressure and cardiac output, resulting in an increased volume capacity.

Sweating is profuse, and plasma volume reduced, the

degree of reduction being related to the amount of fluids given. Since fluid absorption from the gastrointestinal tract may be retarded, there is a tendency toward a disparity between the volume capacity and circulating volume.

Gross water loss is great, and is determined by the temperature, humidity and air movement of the patient's environment, being least in cabinets in which humidity is highest, dry bulb temperature lowest and air velocity least. Tissue fluid loss is determined by the rate of fluid intake, and a critical level exists for each patient beyond which further loss involves risk of peripheral vascular collapse.

The loss of chlorides in sweat and of carbon dioxide through hyperventilation brings about an alkalosis, the degree of which is related to the degree of dehydration permitted to occur.

Provided water, chlorides and carbon dioxide are administered in amounts adequate for replacement of losses, high temperatures (106.7°F) may be safely maintained for long periods (6 to 15 hr).

THE ANTAGONISM OF HYPERTENSION AND ACTIVE TUBERCULOSIS. A. W. Contratto, M.D.

In approximately 32,000 individuals admitted to the Medical Service of the Peter Bent Brigham Hospital, from 1913 to 1936 inclusive, there were 1250 cases of pulmonary tuberculosis, 761 of which were active.

The average age of the entire group was 42.9 years, of the active male group 40.5 years, and of the active female group 35.5 years.

The average blood pressure determinations in the various decades (second to eighth) were from 10 to 15 mm. lower in both the systolic and diastolic readings in the active tuberculous groups than the considered average pressures of normal persons. There were only 6 individuals, or 0.8 per cent, in the active group who had a systolic blood pressure of more than 160 mm. of mercury, and the majority of these cases were not diagnosed as tuberculosis clinically and even at autopsy there was some doubt as to the activity of the lesion.

There were 4 cases of rheumatic heart disease in the active group. Two of these came to autopsy. One had aortic insufficiency and no mitral stenosis, the other had mitral stenosis only. The other 2 cases were diagnosed as mitral stenosis clinically. In the active group there were no cases of angina pectoris or cardiac infarction.

Three hundred and thirty-two cases came to autopsy. One hundred and twenty-four of these were active cases of pulmonary tuberculosis. The average heart weight was much less in the active than in the healed cases, even in proportion to body weight.

It seems that all forms of cardiovascular disease exist only rarely in persons with active tuberculosis.

OBSERVATIONS ON THE FOURTH LEAD OF THE ELECTROCARDIOGRAM. Roger W. Robinson, M.D., A. W. Contratto, M.D., and S. A. Levine, M.D. Presented by Dr. Robinson.

Nine different chest leads were chosen covering the cardiac silhouette to determine if there was one position which would give reliable information in a great majority of instances and could be used as a standard fourth lead. Five hundred tracings were taken on 350 patients, of whom 76 came to autopsy. The old polarity was used. It was found that an upright T wave occurs frequently along the sternum but only rarely at the apex in normal

hearts When an upright T wave occurs as the only abnormality in the fourth lead, it is not reliable evidence for myocardial infarction Large hearts may show no Q wave in any precordial position, except the apex, without myocardial infarction The Q wave may not disappear for fifteen days after an acute anterior infarction, and then it may disappear only at the apex An absent Q wave at the apex is practically always associated with an anterior myocardial infarction The fourth lead may be correctly interpreted in the presence of auricular fibrillation and delayed intraventricular conduction We believe that the apex should be used as the point of application of the electrode for the standard fourth lead.

NOTICES

TUMOR CLINIC, BOSTON DISPENSARY

Each Tuesday and Friday morning from ten to twelve-thirty there is a meeting of the Tumor Clinic of the Boston Dispensary, a unit of the New England Medical Center All kinds of tumors are seen, discussed, and when indicated, treated with radium and high-voltage x ray

Physicians are welcome to visit this clinic and bring a patient to the clinic for diagnosis

AMERICAN BOARD OF OPHTHALMOLOGY

During 1938 the American Board of Ophthalmology will hold examinations as follows

San Francisco, June 13,
Washington, D C, October 8,
Oklahoma City, November 15

Applications should be filed immediately The required number of case reports must be filed at least sixty days prior to the date of examination Application blanks can be procured from Dr John Green, 3720 Washington Avenue, St. Louis, Missouri

FEVER THERAPY

The Peter Bent Brigham Hospital is now equipped to give fever therapy induced by physical means This is under the immediate supervision of Dr John G Gibson, 2nd Physicians desiring to send patients to the hospital for fever therapy should arrange by telephone with the admitting physician, he will furnish information as to charges for such service Advice in regard to the use of fever therapy, suitability of individual patients for it, and so forth, can be obtained by telephoning Dr Gibson at the Peter Bent Brigham Hospital, he should be communicated with before final arrangement for admission of the patient has been made.

POSTGRADUATE INSTITUTE OF THE PHILADELPHIA COUNTY MEDICAL SOCIETY

The Third Annual Postgraduate Institute, offering an intensive and interesting study of diseases of the digestive tract, will be conducted by the Philadelphia County Medical Society from March 28 to April 1 inclusive.

The program to be held in the Bellevue-Stratford Hotel, Philadelphia, has been designed to meet the needs of all members of the profession, but particularly those in general practice.

Physicians from fourteen states having attended last year's institute, an invitation to attend the 1938 session has been extended to the members of all county societies.

Lecturers have been selected from among the foremost teachers in this great medical center While approaching the subject from specialized viewpoints, the presentations will be of a strictly practical nature and of real value to the general practitioner, who finds that digestive conditions occupy a considerable portion of his time.

The Philadelphia County Medical Society, in conducting the institute, is meeting the demands of many physicians who believe that the organized profession should provide them with this type of opportunity for keeping abreast of medical progress, and thus maintaining the highest standards of medical service.

The only charge is a \$5.00 registration fee to cover the institute's expenses

Additional information may be secured from your county society or from the Philadelphia County Medical Society, 21st and Spruce Streets, Philadelphia.

UNITED STATES CIVIL SERVICE EXAMINATION

Junior Scientific Aid (Parasitology), \$1440 A Year

Applications must be on file with the United States Civil Service Commission at Washington, D C., not later than February 28

Applicants must show that they have had at least two years of experience in a zoological laboratory The required experience must have been full time and paid Applicants may substitute one year of study including a course in zoology, successfully completed in a college or university of recognized standing, for one year only of the required experience.

CAMBRIDGE HOSPITAL

The regular clinicopathological meeting of the staff of the Cambridge Hospital will be held at the hospital, 300 Mt. Auburn Street, Cambridge, on Tuesday, February 15, at 8:30 p. m.

All members of the medical profession are cordially invited to attend.

JOSEPH M. WADDEN, M.D., *Secretary*

SOUTH END MEDICAL CLUB

The next regular meeting of the South End Medical Club will be held at the headquarters of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston, on Tuesday, February 15, at 12 noon.

Dr William Dameshek will speak on "Hematological Problems in General Practice."

All physicians are cordially invited to attend.

JOHN B. HALL, M.D., *Secretary*

NEW ENGLAND PATHOLOGICAL SOCIETY

A meeting of the New England Pathological Society will be held in the amphitheater of the Mallory Institute of Pathology, Boston City Hospital, on Thursday, February 17, at 8:00 p. m.

PROGRAM

Alzheimer's Disease. Dr Naomi Raskin.
The Vascular Pattern in Various Lesions of the Human Central Nervous System. Studies with the benzidine stain. Dr Leo Alexander, Dr T. H. Suh and Dr Tracy J. Putnam.

Time Determination of Histopathologic Changes in the Brain Experimental incisions into the brain with transection of meningeal and intracerebral blood vessels in cats Dr Leo Alexander and Dr Hugh P Newbill.

Physicians and medical students are cordially invited to attend.

J B HAZARD, M.D., *Secretary*

NEW ENGLAND SOCIETY OF PHYSICAL MEDICINE

The regular meeting of the New England Society of Physical Medicine will be held at the Hotel Kenmore, Boston, on Wednesday evening, February 16, at 8 00 o'clock.

Dr Robert S Harris will talk on Medical Application of Radiant Energy Discussion by Dr Franklin P Lowry

The Council will meet at 6 00, and dinner will be served in the Empire Room at 6.30

All members of the medical profession are cordially invited to attend.

WILLIAM D McFEE, M.D., *Secretary*

BOSTON SOCIETY OF PSYCHIATRY AND NEUROLOGY

The next meeting of the Boston Society of Psychiatry and Neurology will be held at the Boston Medical Library, Thursday evening, February 17, at 8 15 o'clock

PROGRAM

Chronic Progressive Chorea with Senile Changes in the Cortex and Basal Ganglia Case report. Dr David Rothschild.

The Effect of Benzedrine Sulfate on Sleep, Normal and Drug Induced. Dr Abraham Myerson.

Experiences with Meningiomas of the Brain. Dr Gilbert Horrax.

H. HOUSTON MERRITT M.D., *Secretary*

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY, FEBRUARY 14

TUESDAY FEBRUARY 15

9-10 a m Boston Dispensary Clinicopathological conference Dr R. C. Wadsworth.

10 a m 12.30 p m. Tumor clinic. Boston Dispensary

12 m. South End Medical Club Headquarters of the Boston Tuberculosis Association 554 Columbus Avenue, Boston

4 p m. Boston Tuberculosis Association Hotel Copley Plaza

5 p m. Cutter Lecture on Preventive Medicine Harvard Medical School Amphitheater Building E.

WEDNESDAY FEBRUARY 16

9-10 a m. Boston Dispensary Hospital case presentation Dr S J Thannhauser

12 m Clinicopathological conference. Children's Hospital Amphitheater

8 p m. New England Society of Physical Medicine Hotel Kenmore Boston

THURSDAY FEBRUARY 17

8.30-9.30 a m Exchange visit, surgical and orthopedic staffs of the Peter Bent Brigham and Children's hospitals held this week at the Children's Hospital.

9-10 a m Boston Dispensary Hyperventilation Syndromes Dr Maurice Sokolow

4 p m. New England Pathological Society Amphitheater of the Mallory Institute of Pathology Boston City Hospital

8 15 p m. Boston Society of Psychiatry and Neurology Boston Medical Library 8 Fenway Boston

FRIDAY FEBRUARY 18

9-10 a m Boston Dispensary Some Recent Developments in Purpura and Hemophilia Dr Frederick J Poble.

10 a m. 12.30 p m. Tumor clinic Boston Dispensary

12 m Clinical meeting of the Children's Medical Service, Massachusetts General Hospital Ether Dome

SATURDAY FEBRUARY 19

9-10 a m Boston Dispensary Hospital case presentation. Dr S J Thannhauser

10 a m 12 m. Staff rounds at the Peter Bent Brigham Hospital Conducted by Dr Henry A Christian

SUNDAY FEBRUARY 20

4 p m. Illustrated public health lecture Faulkner Hospital auditorium. Progress in Dental Surgery Dr Kurt H Thoma

4 p m. Free public lecture. Harvard Medical School amphitheater of Building D Overweight and Underweight. Dr F Dennette Adams.

4 p m. Free public lecture Beth Israel Hospital Boston in conjunction with the Women's Auxiliary Dangers that Lurk in Cosmetics Dr Jacob J Schwartz

BOOK REVIEW

Artificial Fever Produced by physical means, its development and application Clarence A. Neymann. 294 pp Springfield and Baltimore Charles C Thomas, 1937 \$6.00

The advance in artificial fever as a means of treatment in many diseases has been so rapid that most of the literature has necessarily appeared in medical journals. Some of this, having been collected and evaluated, is now published in monograph form. The author, Dr Neymann, was one of the pioneer workers in this field, having begun his investigations as early as 1927 and published his first paper September 1, 1929. It would appear that he was the first to use high frequency currents in man for the purpose of treating disease. His work was done originally at the Cook County Psychopathic Hospital and later at the Northwestern University Medical School. His book consists of an adequate historical introduction to the subject, excellent descriptions of the technic of electropyrrexia and well written chapters on the physiology of hyperpyrexia due to various agents, the effects of artificial fever upon diseases such as dementia paralytica, other forms of syphilis, multiple sclerosis, chorea minor, arthritis, gonorrhea and asthma, and finally, an evaluation of his own results as compared with those of others. In addition, he gives an extensive bibliography up to January 1, 1937, listing over 550 references.

The book may be read with many points of view in mind. Those interested in the history of artificial fever will find an adequate account of not only the more recent methods based upon electricity, but the older ones, particularly balneotherapy, used from very ancient times. Of most interest, perhaps, in the historical field are his account of patients bathing in a bath of hot water in Japan, where the body temperature is raised by this method to as high as 104°F, and the forgotten demonstration by Philipps, in 1883, that by immersing himself in hot water, he raised his own temperature to 103°F. Dr Neymann gives Philipps the credit, therefore, of being the originator of hyperpyrexia produced by physical agents.

The physiologist will be interested in the excellent

chapter on the bodily effects of hyperpyrexia, in relation to the velocity of blood flow and on the heart, sodium chloride excretion, blood sugar, and so forth. All these subjects, others, are treated in considerable detail. Another of the book, which concerns the technic of electrical, in charts and photographs as well as with the various types of methods which have in the last ten years. The author has tried out all the methods which are described, beginning with diathermy, first reported in 1929, and followed by thermotherapy, electromagnetic induction, electric blanching heat and hot-air cabinets, with his final in the last two years, of a combination of air-cooled cabinets and electromagnetic induction. This has to be the safest and surest way to raise the temperature of the body and keep it at a constant level as desired.

Finally, the book will be useful to the clinician. There are individual chapters on separate diseases and the results of treatment. Dementia paralytica has a record, for in early cases selected for treatment the recovery rate is very high, perhaps up to 80 per cent. In institutionalized and deteriorated patients, the recovery rate is much lower, but even in this group recovery may reach as high as 30 per cent, and another 30 per cent will show decided improvement. After hyperpyrexia, the use of tryparsamide and other heavy salts is recommended. The results of treating other diseases, of syphilis of the central nervous system are not so satisfactory, although the author believes that, in cases of tabes dorsalis, artificial fever is a safe and practical method of treatment that promptly alleviates the lancinating pains and crises in a large percentage of the cases. In the treatment of primary optic atrophy due to syphilis, in the author's opinion, in an experimental stage, striking results have been obtained. The same may be said of the treatment of primary and secondary syphilis, although improvement is readily noted, it would seem that artificial fever alone will not eradicate the disease. The author is somewhat encouraged by his treatment of cases of multiple sclerosis and feels that the results with hyperthermia are better than those with other forms of therapy. In chorea minor the disease is promptly aborted in the vast majority of the cases, although recurrences may occur in a few after the treatment is over. Dr Neymann feels that artificial fever at present is the treatment of choice for Sydenham's chorea. It also seems to be a specific for the treatment of gonorrhea, but there are other factors to be considered and the elaborate technic of treatment tends to forestall the use of this method when easier forms of treatment are at hand. It is thought, in addition, that electropyrrexia may have some influence on asthma.

In general, it is too early to evaluate this form of treatment in any of the diseases except, possibly, dementia paralytica. The author takes a broad stand on this point in spite of his intensive work on this form of treatment and his great interest in it. Although the subject is advancing so rapidly that this monograph will soon be out of date and require a second edition, nevertheless the book is one of great value for its historical perspective and for its view of the subject at the present time, seen through the eyes of an expert. For the details of treatment, the physiologic effects, and a review of the literature, this book can be highly recommended. The author would be the first to admit that it is not the final word on the subject, for advances have already been recorded since he was able to finish his manuscript, a few months ago.

NUMBER 7

THE LOSS OF BLOOD IN CERTAIN STANDARD OPERATIONS FOR MALIGNANT DISEASE

WESTON T. BUDDINGTON, M.D.,* AND GRANTLEY W. TAYLOR, M.D.†

WRENTHAM AND BOSTON

THE determination of the amount of blood lost in operations is of great interest and value. The amount becomes of major importance in a poor-risk patient with malignant disease. A knowledge of the amount lost in certain types of operative procedures not only helps the surgeon to plan the preoperative and postoperative treatment, but also guides him in the choice of a technic.

Relatively little material dealing with this subject has been published. Gatch and Little¹ investigated the amount of blood lost in several of the commoner operations, and presented their results and method in 1924. Collier and Maddock² using the same method, made additional studies to determine what part the loss of blood played in the dehydration attendant upon operations. Recently Pilcher and Sheard³ have reported a varied series from the Mayo Clinic.

The method which we have employed to determine loss of blood is based on that of Gatch and Little,¹ although modified according to the recommendations of Stewart.⁴ Just before operation, from 4 to 6 cc. of blood is withdrawn from a vein and mixed with a few milligrams of heparin. This prevents clotting, without appreciably diluting the blood. Exactly 1 cc. is mixed with known amounts of N/10 hydrochloric acid, to form acid hematin. This constitutes the "standard," generally in a 1:500 dilution.

With rare exceptions, the skin is prepared with 3.5 per cent tincture of iodine. After drying, this is removed with alcohol, to prevent its being absorbed by the sponges and drapes used during the operation, and thus disturbing the calculation of loss of blood. The sponges upon being discarded are dropped into pails of distilled water so that the blood will not dry and cake. All drapes, gowns and instruments stained with blood are washed in distilled water until the hemoglobin

has been extracted. The sponges and linen are wrung dry by being passed through a wringer. Tissues removed from the body are washed free of gross blood. The total volume of the solution of laked blood thus obtained is accurately measured, and a measured sample is converted into acid hematin by the addition of hydrochloric acid. This is compared with the standard in a colorimeter. The amount of blood lost is easily calculated from these data.

As judged by our own control tests and those of others, the method is accurate, possibly within 5 per cent or at most 10 per cent of the actual loss. It is impossible to recover all the blood spilled during a major surgical procedure, except perhaps in transurethral resections of the prostate where all the bloody irrigating fluid can be saved.

Our object was twofold: to ascertain the amount of blood lost in some of our standard operations, and to discover the factors affecting this amount. Incidentally, our studies have emphasized in the surgeon's mind the necessity of hemostasis, and have confirmed the advantage of a given technic and the advisability, at times, of postoperative transfusion. The minimum, maximum and average loss of blood for a variety of operations are shown in Figures 1 and 2.

The wide difference in the 2 cases of vaginal hysterectomy accompanied by perineorrhaphy merits comment. In the case where the loss of blood was slight, the patient had a small uterus, which was easily delivered, and the operation was carried out with close attention to hemostasis. The high loss of 935 cc. occurred in a slightly obese patient who had previously had 4800 r units of radiation applied over the operative area, the resulting fibrosis rendering the operation technically difficult. Pilcher and Sheard³ have reported 1 case of vaginal hysterectomy, with no mention of perineorrhaphy, in which the loss of blood amounted to about 680 cc.

The maximum and minimum figures for abdominal hysterectomy are interesting, both opera-

*Assistant visiting surgeon, Pondville Hospital.

tions were performed by the same surgeon. The average of all the cases is close to that of similar ones recorded elsewhere. In almost every case in our series the operation included removal of both tubes and ovaries and the appendix.

There was virtually no difference between the amount of blood lost in a total gastric resection

Figure 1 Amount of blood loss in certain standard operations

and that lost in subtotal resections, 2 cases of partial resection are recorded in the literature, one with a loss of 274 cc. and the other with a loss of 232 cc. From all these we may conclude that the desirability of postoperative transfusion in the average gastric resection rests on other grounds than the amount of blood lost at operation.

The results in resection of the rectum are significant. In this procedure we separated the blood

Figure 2 Amount of blood loss in certain standard operations

lost in the abdominal excision from that lost in the perineal. The latter was carried out with the patient either in a lateral position or in that employed for lithotomy. It was at once apparent that most of the loss arose from the perineal excision, even when due allowance was made for blood which had collected in the pelvis in the interval between the two parts of the operation and was thus included in the loss at the time of the second operation. The shock which occasionally developed during the latter part can be

attributed in great degree to this sudden loss of a large amount of blood. The total loss is striking, and strongly supports our policy of giving at least one transfusion, and not infrequently two, in such combined procedures. Our routine practice is to have a continuous intravenous saline clysis started at the beginning of the operation, the citrated blood for transfusion being added when the posterior excision is begun.

The average loss for 11 cases of radical mastectomy, all performed according to the same technique, was 430 cc. We were surprised to find in the literature figures for this operation ranging from 725 to 1272 cc. Our lowest loss (134 cc.) occurred in a radical mastectomy performed on a thin, elderly woman with a small atrophic breast. The average systolic blood pressure during the operation was equivalent to only 70 mm of mercury. Careful attention was given to hemostasis throughout the operation, which lasted one hour and fifty minutes.

The technic employed for radical mastectomy is described elsewhere.⁵ It consists essentially in a modification of the transverse axillary dissection of Rodman.⁶ The important steps which keep the loss of blood at a minimum are: first, sharp dissection with constant traction, which allows the vessels to be clamped before cutting, particularly the many tributaries of the axillary vein and artery; secondly, deferred removal of the sternocostal portion of the pectoralis major muscle and fascia until the remainder of the dissection has been completed. The latter permits the operator to expose the perforating branches of the internal mammary vessels so that they may be clamped before cutting. The amount of blood that spurts from one of these larger vessels in a very short time is considerable.

During the study, record was kept of several factors which it was felt affected the amount of blood lost, for example, the patient's blood pressure and physique, and the speed and skill of the operator. Correlation of these factors resulted in certain general deductions. A high blood pressure during the operation of course increased the rate of blood flow from the ends of severed vessels. Obesity contributed to a higher blood loss in two ways: first, the additional amount of tissue to be dissected necessitated cutting a great many additional vessels; secondly, accurate and secure application of hemostatic clamps was more difficult owing to the friability of vessels in adipose tissue. When all the factors tending to decrease blood loss operate together, the amount may be unusually small, for example, the 134 cc for a radical mastectomy referred to above. The technic and skill of the surgeon and his assistants constitute the most significant factor, often, however, a combination

of adverse circumstances—technical difficulties, obesity, hypertension and the like—more than offset the advantages of an efficient operating team. While the amount of blood lost has a distinct bearing on the development of postoperative shock, other influences are also powerful. The character of the anesthesia, the manipulations, the time consumed by the operation, cooling, the rapidity of blood loss and the general condition of the patient all have an important bearing. It is not surprising, therefore, that we were able to establish only a gross correlation between the amount of loss and the clinical evidence of shock. Many of the other factors, however, are similarly under the control of the operating surgeon, and it is probable that the amount of blood lost serves as a measure of the care and skill with which he has carried out his operation, and of the effectiveness of the precautions he has exercised against the development of operative shock.

SUMMARY

- 1 The loss of blood attendant upon certain standard operations for malignant disease was determined, and the results are recorded
- 2 Factors tending to increase or decrease blood loss are briefly discussed
- 3 Knowledge of the amount of blood lost in certain types of operations aids the surgeon in planning his operative, preoperative and post-operative treatment

THE USE OF SULFANILAMIDE IN GONORRHEA IN THE MALE

A Preliminary Report and a Warning

WALTER M. BRUNET, M.D.,* CHARLES H. REINHARDT, M.D.,† AND NORMAN D. SHAW, M.D.‡

CHICAGO

THIS preliminary report relates to the use of sulfanilamide as an adjuvant in the treatment of several hundred acute and chronic, anterior and complicated, cases of gonorrhea in the male. We have not depended solely upon sulfanilamide for a cure. In acute anterior infections local injections of a mild antiseptic have been given, and in the posterior cases remedies of proved worth have been administered in conjunction with the compound. A number of these patients have been carefully observed for a sufficient period of time for recognized tests of cure to be carried out before they were discharged, and for an evaluation of the treatment. The patients have not been selected, and the clinical study is still in progress and will be reported in detail at a later date.

Within the past twenty years about a dozen "specifics" for gonorrhea have been proclaimed. The most recent one, sulfanilamide, follows close upon the Corbus-Ferry filtrate, which failed miserably as a cure. Despite reports of remarkable cures from the use of sulfanilamide in gonococcal infections in the male, we believe that this infection will continue for many years to be the medical riddle of the sphinx. We believe that sulfanilamide

is, and should be, regarded only as an experimental and speculative remedy until a larger number of adequately controlled and correlated clinical studies have been reported. The recent papers giving the results of the use of the drug in specific urethritis have been wholly lacking in completeness, and not a single contributor has mentioned adequate controls or extended supervision. Therefore, on the rather meager grounds of insufficient clinical trial and observation the medical profession is deluged with propaganda announcing another cure for gonorrhea. In a recent leaflet one of the large drug houses describes the action of the drug as follows: "In gonorrhea the discharge disappears within a few days, and smears usually become negative within a week." This is quite simple, and with such a medicament there is surely no occasion for the guiding hand of a physician. Several recent reports in the literature have been to the effect that the toxicity of the drug in man and animals is low. We have seen a large number of patients who showed some reaction to it, but whether these manifestations are toxic in origin or are due to an idiosyncrasy is not known.

Within the past few months there have appeared reports of the use of Elixir of Sulfanilamide which has caused scores of deaths, the fatalities were apparently due to the diethylene glycol in which the drug was dissolved. Sulfanilamide is one of

From the Public Health Institute, 159 North Dearborn Street, Chicago.

†Staff member, Urological Department, Public Health Institute.

a large number of chemical compounds which contain the benzene ring, and it is well known that these products and the closely allied phenyl derivatives often exhibit a harmful effect upon the bone marrow and other blood-making organs. Several authors report the successful use of the medication in meningitis, bacteremia of puerperal origin, pneumonia and influenza. However, dangerous and even fatal blood changes such as acute hemolytic anemia, agranulocytosis and sulfhemoglobinemia have followed its administration. While these alterations are not often encountered, they occur with sufficient frequency to demand the most careful observation and control of the patient. The indiscriminate prescribing of sulfanilamide by physicians is to be frowned upon, and its direct sale over the drugstore counter is to be severely condemned.

Sulfanilamide in our hands has not yet proved to be a specific for gonorrhea in any stage of the disease, but we do find that its conservative use has been of benefit in a number of cases. We recommend that not more than 40 gr be taken daily. We prescribe two 5-gr tablets and an equal amount of bicarbonate of soda, to be taken every three hours. Even this small amount causes unexpected symptoms in a number of patients. We suggest that larger doses be withheld until the pharmacology of the drug has been more thoroughly studied and its action understood, for it is possible that its injudicious use may induce mortality in a disease which ordinarily should have none.

In acute anterior gonorrhea we have observed a number of patients in whom the drug produced fairly prompt changes in the character and consistency of the discharge, but organisms were readily demonstrated for many days in the stained slides. We expect about 5 per cent of our patients with an anterior infection to recover from their disease promptly with mild conservative treatment. By the addition of sulfanilamide to our armamentarium this percentage will probably be doubled. However a number of our patients who have taken large doses of sulfanilamide for many days have developed severe complications, such as prostatitis, vesiculitis and epididymitis, and have had a stormy recovery. We have treated others in whom an apparent carrier state was produced, in these the symptoms almost completely disappeared, but there remained a residual watery but persistent urethral discharge in which typical intracellular gonococci were found. These patients afterward respond slowly to any method of therapy.

Sulfanilamide appears to be of value in lessening the pain and discomfort in acute posterior extensions, and in some cases there is an apparent short-

ening of the course of the disease. We have seen several patients with chronic, deep-seated infections which had become stationary under other forms of therapy who began to improve within a day or two after taking the drug. The urethral discharge decreases rapidly, the second-glass specimen of urine clears, the pus content of the prostatic secretion diminishes, and a complete recovery follows. The most striking results we have encountered were in 2 patients with acute gonococcal arthritis. In one young man the symptoms were relieved in twelve hours, the redness and swelling of the wrist and fingers being reduced and the pain entirely relieved, and he made an uneventful recovery. In the second patient there was not quite the same dramatic response as in the first, but a complete recovery was made within a few weeks.

The drug probably acts by causing some change in the organism, which permits phagocytosis, and at the same time the growth of the bacteria is inhibited. In many well-developed anteroposterior infections the drug apparently has no effect on the course of the disease.

We have had a large number of patients with mild reactions. These have consisted of anorexia, gastric distress, headache, dizziness, ringing in the ears, dermatitis and elevation of temperature. One patient stated that he became "unconscious" after taking the drug for twenty-four hours. In 2 cases elevated, reddish-brown skin lesions were observed. In several patients with a dermatitis the eruption was present on the palms of the hands but the mucous membrane of the mouth was not involved.

Sulfanilamide may become a very valuable remedy in urological practice, but overenthusiastic manufacturers must not continue to impose upon the credulity of the general practitioner, on the other hand, skeptical physicians should not minimize the value of the drug without sufficient trial. The place the compound will occupy in medical practice must depend upon time and the unbiased sifting of divergent clinical experiences and opinions. Not until then will it be possible to evaluate correctly the use of the drug in the treatment of gonorrhea. We fear that the unwarranted publicity from pharmaceutical concerns, which is deluging the physicians of the country, may prove so enticing that many practitioners will succumb to these optimistic and alluring statements and not give the careful scientific thought to this new drug that is demanded.

When optimism takes precedence over scientific effort, the scientist is left out of the experiment. The physician should be more analytical of himself and his actions. There is hardly a doubt that we are regressing in our scientific concept of gonor-

rhea and its cure when we permit the glowing but unproved statements in leaflets of chemical concerns to make us cast aside time-honored and reliable measures for something which is said to be

newer and surer. The greater the ignorance, the greater the dogmatism." There is not a physician in this country who would not welcome the day that a true gonococcicide is discovered!

SERUM-PROTEIN STUDIES IN HYPERTHYROIDISM

ELMER C. BARTELS, M.D. *

BOSTON

THE present study of the serum proteins in hyperthyroidism was undertaken because of conflicting reports in the current literature, and in order to obtain additional information regarding the disturbances in general body metabolism in this disease.

Di Benedetto¹ (1933) made a comparative study in 15 normal women and 15 women who had hyperthyroidism and whose basal metabolic rates were more than plus 20 per cent. In cases of hyperthyroidism the value for total protein did not vary from normal, the serum-albumin content was increased a little, the globulin content was increased a little more than the serum albumin, and the albumin-globulin ratio was elevated. He reported that these results were similar to those observed in a dog with hyperthyroidism produced experimentally by the ingestion of thyroid substance. No constant parallelism was found between the variation of the metabolism and the serum-protein content.

Olivetti and Bobbio² studied the proteins of the blood in individuals suffering from disease of the thyroid gland. They reported a tendency to hypoproteinemia with lowering of the albumin-globulin ratio in cases of hyperthyroidism. They attributed this alteration in the value for proteins to a specific influence of the thyroid gland on the regulation of the body-protein mixtures through the neuro-endocrine system.

Labbé, Nepveux and Ornstein³ (1932) reviewed the literature and found conflicting reports. An increase in the total protein content was noted by some observers, changes in the albumin-globulin ratio with an unchanged value for total protein by others, and entirely normal conditions by still others. The study made by Labbé, Nepveux and Ornstein revealed no deviation from the normal. No relation was found between the values for the proteins and the severity of the disease as evidenced by the basal metabolic rate.

Another reason for the present study was to obtain further evidence of changes in hepatic func-

tion in hyperthyroidism. Sufficient clinical and pathological evidence is at hand to indicate that the liver undergoes changes in this disease,^{4, 5, 6, 7, 8, 9} and in recent articles significant changes in the serum-protein content in diseases of the liver have been reported. Tumen and Bockus,¹⁰ in a recent report of the changes in the value for the serum proteins in hepatic disease, corroborated the work of most other observers, who showed a lowering of the serum-albumin content with an elevation of the serum-globulin content and a reversal of the albumin-globulin ratio in this condition. The lowering of the value for serum albumin was the most consistent change noted, elevation in the serum-globulin content and lowering of the albumin-globulin ratio occurred, but were not so constant or significant as the former. This change in the value for serum proteins was thought to be due to alteration in the function of the liver, either in the manufacture of albumin or in the maintenance of its proper level in the blood.

Snell,¹¹ in a recent editorial on the subject of the serum proteins in hepatic disease, asserted that evidence at hand indicated the liver was responsible for the reduction in the plasma proteins, particularly serum albumin. He reviewed experimental evidence that the liver figures strongly in the maintenance of stored and circulating protein. In considering the diagnostic and prognostic significance of the level of the plasma proteins, he concluded that a reversible reaction is apparently possible, since with recovery in the liver the protein content of the serum returns to normal.

MATERIAL

Determination of the serum-protein content by the micro-Kjeldahl method was carried out in 59 cases of hyperthyroidism which exhibited a wide range of toxicity. In 31 cases (Table 1) the level of the total protein was determined on three occasions—on admission to the hospital, just before operation (after a preoperative course of treatment, usually of ten days' duration) and three months after operation, when the usual postoperative determination of the metabolic rate is made. The

Adenomatous goiter

serum-albumin and serum-globulin contents also were determined separately on admission in 11 cases, just before operation in 10 cases and three months after operation in 5 cases. In an additional group of 28 cases (Table 2) the total serum-protein content was obtained on admission and before operation, but not after operation. The serum-albumin and serum-globulin contents were determined separately on admission in 8 cases and pre-operatively in 9. The determination of the serum

RESULTS

The average total protein content determined on admission to hospital in 43 cases of primary hyperthyroidism was 6.3 gm for each 100 cc of serum, in 14 cases of adenomatous goiter the value was the same. The effect of hyperthyroidism on the total serum-protein content is apparently the same in both types of disorder.

The distribution of cases and the range of determinations of the total serum-protein content

Figure 1 Total serum protein content

proteins on examination three months after operation (Table 1) may be considered to represent a control series, since by this time the patients had regained their health and the basal metabolic rate had returned to normal. That this assumption is correct is also shown by the fact that the determinations made at this time were well within the range of normal according to laboratory standards.

A study of the hepatic function by means of the excretion test of hippuric acid by the method of Quick^{12, 13} was carried out in most of the cases in this series, as indicated in Tables 1 and 2. This procedure permitted a comparison of two observations relating to the condition of the liver in the cases studied.

on admission, immediately before operation and three months after operation are shown in Figure 1. It should be remembered that the determinations made three months after operation were carried out at a time when the patients had recovered from the disease and were considered normal. The average level for total serum protein on admission was 6.4 gm for each 100 cc, with a range of from 4.9 to 8.3 gm. In 63 per cent of the cases the values for the total serum proteins were below 6.6 gm., which is the lowest level in the normal range. In only 1 case was the level for total serum protein above the average normal of 7.8 gm.

The determinations made after the ten-day pre-operative preparation showed that little change had taken place during this period. The average

value was 66 gm, and the range of determinations remained the same. An increase in total serum protein content occurred in 47 cases, however, and at this time in only 37 per cent were the determinations below 66 gm.

Three months after operation the range of the total serum-protein determinations in 31 cases was found to be between 66 and 88 gm, with an average of 78 gm—a normal variation and an average value.

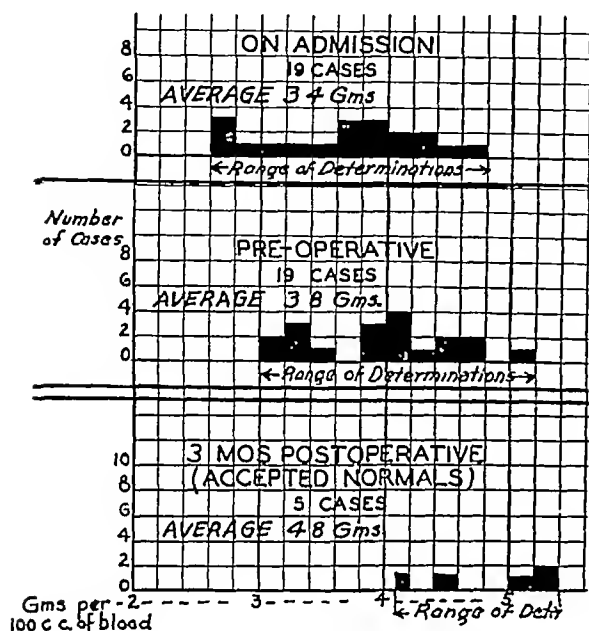

Figure 2 Serum-albumin content

The serum-albumin (Fig 2) on admission ranged between 26 and 47 gm, with an average of 34 gm for each 100 cc. In 73 per cent (14) of 19 cases the determinations were below 41 gm, the lowest figure in the normal range. Before operation the average serum-albumin content was 38 gm, with a range of from 3 to 51 gm.

At this point in only 52 per cent (10 of 19 cases) were the determinations below the accepted normal value. The average serum-albumin content three months after operation was 48 gm, with a range of from 41 to 53 gm.

The average serum-globulin content (Fig 3) was found to be practically the same on admission, before operation and three months after operation. The figures were 26, 26 and 25 gm., respectively. With one exception the range also remained the same in the three instances. A single determination made on admission was 1.3, compared to the lowest normal of 1.7 gm.

The average albumin-globulin ratios, expressed as the figure obtained by dividing the amount of albumin by that of globulin, were 1.4 and 1.5, respectively, on admission and before operation as

compared to the normal average of 2.2 (Fig 4). Hence, the range was reduced on admission and preoperatively, the low figure on admission was 0.8.

No parallelism was found between the level of the serum proteins and the duration of the hyperthyroidism or the amount of weight lost during the course of the disease. In patients who had had hyperthyroidism for only a few months, the levels for proteins were as low as in those who had had it for years. As for the relation of serum-protein content to loss of weight, the patient who had the highest total serum-protein content—8.3 gm.—had not lost weight, on the other hand, the patient with the lowest protein—4.9 gm.—had lost only 10 lb.

No relation was found between the level of the total serum protein and the degree of elevation

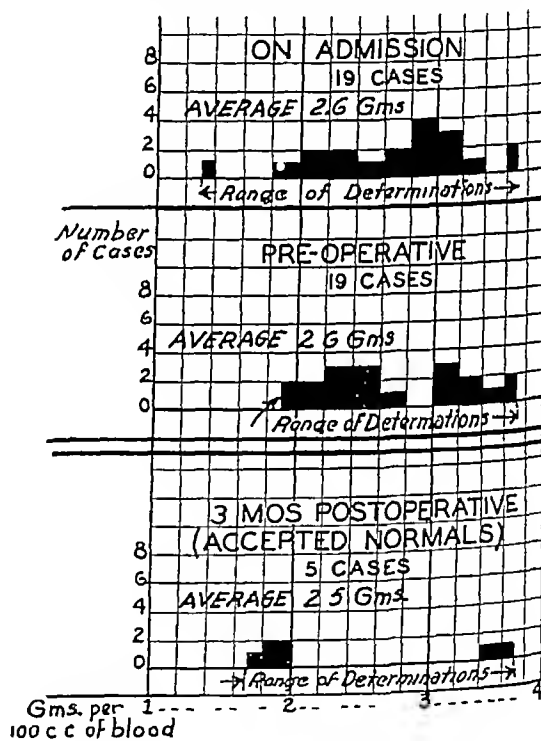

Figure 3 Serum globulin content

of the basal metabolic rate. But in comparing these two factors certain features were noted. In some of the cases of severe adenomatous goiter the basal metabolic rate was only slightly elevated and the total serum-protein content was moderately low. It has nevertheless been recognized that the basal metabolic rate in cases of adenomatous goiter with hyperthyroidism does not always indicate the degree of toxicity, as it does in primary hyperthyroidism. Again, of the 3 patients in whom the value for the total serum proteins was only slightly reduced and the basal metabolic rates were high,—more than plus 70,—2 had

not lost weight and I had diabetes mellitus as a complicating factor. It has been recorded in a recent paper¹⁴ that the hepatic function is not greatly disturbed in cases of hyperthyroidism which are complicated by the presence of diabetes.

The excretion test of hippuric acid by the method of Quick has received considerable clinical trial as a means of determining the functional capacity of the liver, and has proved satisfactory. Since

test determines a specific type of hepatic function, and that excretion test of hippuric acid is an index to the function concerned with carbohydrate metabolism (glycogenic function), while the level of serum protein is an index to the function concerned with protein metabolism (proteogenic function).

RELATION OF SERUM-PROTEIN LEVEL TO SEVERITY OF HYPERTHYROIDISM

When study of a case of hyperthyroidism shows unusual severity of the disease, subtotal thyroidectomy should be performed in two stages rather than in one. As this decision is of utmost importance to the patient and is conditioned by the clinician's opinion, a further search for some criterion was carried out by comparing the level of the total serum proteins on admission with the type of surgical procedure performed. In Figure 5 it is shown that of the 25 cases in which

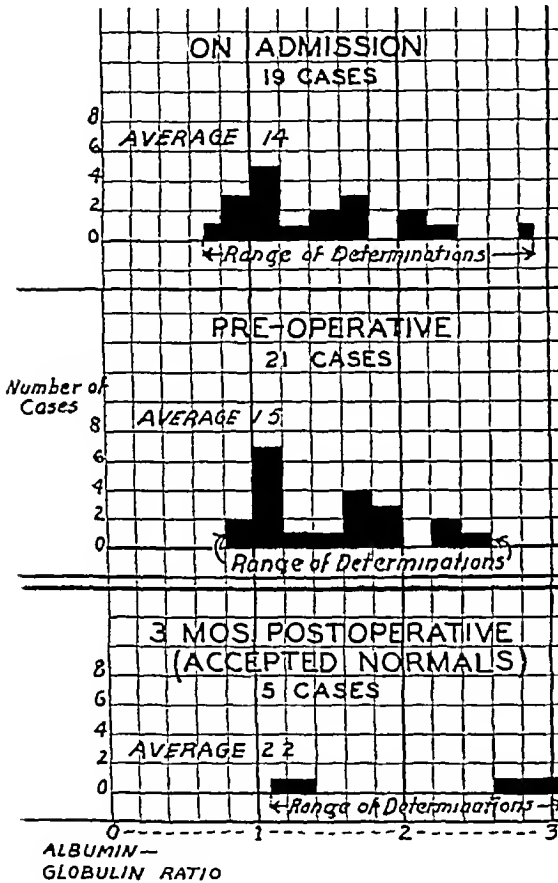

Figure 4 Albumin globulin ratio

the levels for the serum proteins gave information as to the condition of the liver, it was suspected that there might be a corresponding change in the two tests. It was found that the relation was only approximate. In 12 cases of hyperthyroidism in which the values for total serum proteins were below 6 gm per 100 cc, the value for excretion of hippuric acid was 1.95 gm., as compared with 9 cases in which the total serum-protein content was more than 7 gm and the average excretion of hippuric acid was only slightly greater, 2.11 gm.* This failure to demonstrate a direct relation is difficult to explain. It may be, of course, that each

*The normal value for the excretion of hippuric acid is approximately 3 gm.

NUMBER OF CASES	TYPE OF OPERATION	AVERAGE SERUM PROTEIN IN MGS.	NUMBER OF CASES HAVING TOTAL SERUM PROTEIN BELOW 6 MGS.
25	SUBTOTAL THYROIDECTOMY	6.5	4 (16%)
32	HEMI-THYROIDECTOMY	6.2	11 (34%)

Figure 5 Serum protein content in cases in which subtotal thyroidectomy or hemithyroidectomy was carried out

hyperthyroidism was sufficiently mild clinically to permit subtotal thyroidectomy, the average total serum-protein content was 6.5 gm per 100 cc. In only 4 cases, or 16 per cent, was the total protein content less than 6 gm. In 32 cases in which the hyperthyroidism was of sufficient severity to require a hemithyroidectomy as the first operation, the average value for total serum protein was 6.2 gm per 100 cc, in 11 of these cases, or 34 per cent, the total serum-protein content was less than 6 gm. Again, of the 15 cases in which the total protein content was less than 6 gm., hemithyroidectomy was done in 73 per cent. This indicates a direct relation between the clinical severity of the hyperthyroidism and the level of the total serum protein.

In 5 cases (Table 1, Cases 23 and 30, Table 2, Cases 1, 17 and 26) the serum-albumin content was 3 gm or less, the lowest total being 2.6 gm. Primary hyperthyroidism was present in 4 cases, adenomatous goiter with hyperthyroidism in 1, and in all 5 cases two operations were performed. The average basal metabolic rate in these cases was plus 61 per cent, plus 44 was the average for the entire series. The average values for total serum

value was 66 gm, and the range of determinations remained the same. An increase in total serum protein content occurred in 47 cases, however, and at this time in only 37 per cent were the determinations below 66 gm.

Three months after operation the range of the total serum-protein determinations in 31 cases was found to be between 66 and 88 gm, with an average of 78 gm—a normal variation and an average value.

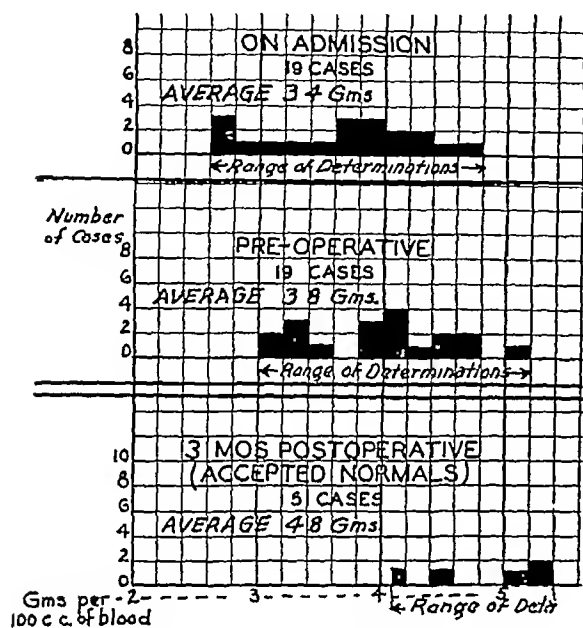

Figure 2 Serum-albumin content

The serum-albumin (Fig 2) on admission ranged between 26 and 47 gm, with an average of 34 gm for each 100 cc. In 73 per cent (14) of 19 cases the determinations were below 41 gm, the lowest figure in the normal range. Before operation the average serum-albumin content was 38 gm., with a range of from 3 to 51 gm.

At this point in only 52 per cent (10 of 19 cases) were the determinations below the accepted normal value. The average serum-albumin content three months after operation was 48 gm, with a range of from 41 to 53 gm.

The average serum-globulin content (Fig 3) was found to be practically the same on admission, before operation and three months after operation. The figures were 26, 26 and 25 gm., respectively. With one exception the range also remained the same in the three instances. A single determination made on admission was 13, compared to the lowest normal of 17 gm.

The average albumin-globulin ratios, expressed as the figure obtained by dividing the amount of albumin by that of globulin, were 1.4 and 1.5, respectively, on admission and before operation as

compared to the normal average of 2.2 (Fig 4). Hence, the range was reduced on admission and preoperatively, the low figure on admission was 0.8.

No parallelism was found between the level of the serum proteins and the duration of the hyperthyroidism or the amount of weight lost during the course of the disease. In patients who had had hyperthyroidism for only a few months, the levels for proteins were as low as in those who had had it for years. As for the relation of serum-protein content to loss of weight, the patient who had the highest total serum-protein content—83 gm—had not lost weight, on the other hand, the patient with the lowest protein—4.9 gm—had lost only 10 lb.

No relation was found between the level of the total serum protein and the degree of elevation

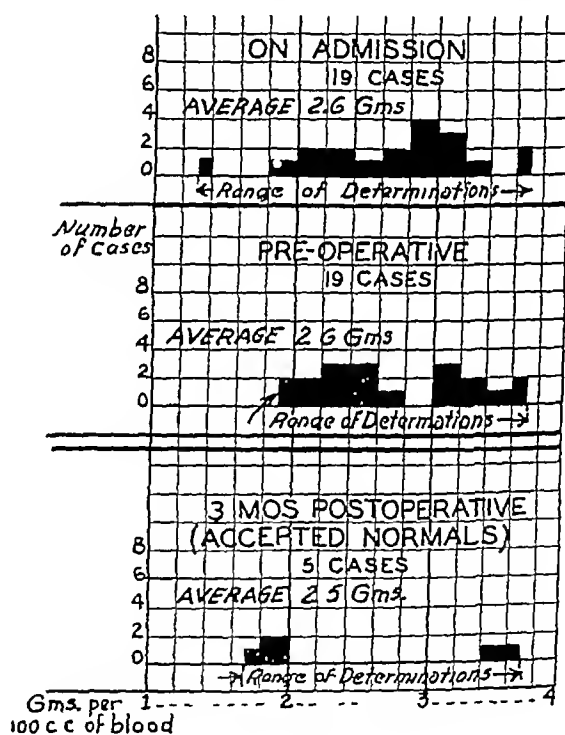

Figure 3 Serum globulin content

of the basal metabolic rate. But in comparing these two factors certain features were noted. In some of the cases of severe adenomatous goiter the basal metabolic rate was only slightly elevated and the total serum-protein content was moderately low. It has nevertheless been recognized that the basal metabolic rate in cases of adenomatous goiter with hyperthyroidism does not always indicate the degree of toxicity, as it does in primary hyperthyroidism. Again, of the 3 patients in whom the value for the total serum proteins was only slightly reduced and the basal metabolic rates were high,—more than plus 70,—2 had

not lost weight and 1 had diabetes mellitus as a complicating factor. It has been recorded in a recent paper¹⁴ that the hepatic function is not greatly disturbed in cases of hyperthyroidism which are complicated by the presence of diabetes.

The excretion test of hippuric acid by the method of Quick has received considerable clinical trial as a means of determining the functional capacity of the liver, and has proved satisfactory. Since

test determines a specific type of hepatic function, and that excretion test of hippuric acid is an index to the function concerned with carbohydrate metabolism (glycogenic function), while the level of serum protein is an index to the function concerned with protein metabolism (proteogenic function).

RELATION OF SERUM-PROTEIN LEVEL TO SEVERITY OF HYPERTHYROIDISM

When study of a case of hyperthyroidism shows unusual severity of the disease, subtotal thyroidectomy should be performed in two stages rather than in one. As this decision is of utmost importance to the patient and is conditioned by the clinician's opinion, a further search for some criterion was carried out by comparing the level of the total serum proteins on admission with the type of surgical procedure performed. In Figure 5 it is shown that of the 25 cases in which

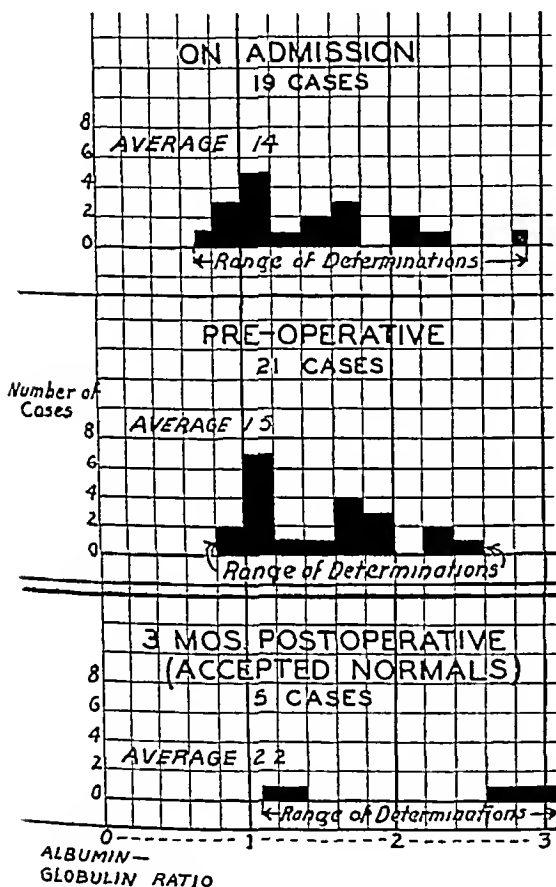

Figure 4 Albumin globulin ratio

the levels for the serum proteins gave information as to the condition of the liver, it was suspected that there might be a corresponding change in the two tests. It was found that the relation was only approximate. In 12 cases of hyperthyroidism in which the values for total serum proteins were below 6 gm per 100 cc., the value for excretion of hippuric acid was 1.95 gm, as compared with 9 cases in which the total serum-protein content was more than 7 gm and the average excretion of hippuric acid was only slightly greater, 2.11 gm.* This failure to demonstrate a direct relation is difficult to explain. It may be, of course, that each

*The normal value for the excretion of hippuric acid is approximately 3 gm.

NUMBER OF CASES	TYPE OF OPERATION	AVERAGE SERUM PROTEIN IN MGS.	NUMBER OF CASES HAVING TOTAL SERUM PROTEIN BELOW 6 MGS.
25	SUBTOTAL THYROIDECTOMY	6.5	4 (16%)
32	HEMITHYROIDECTOMY	6.2	11 (34%)

Figure 5 Serum protein content in cases in which subtotal thyroidectomy or hemithyroidectomy was carried out.

hyperthyroidism was sufficiently mild clinically to permit subtotal thyroidectomy, the average total serum-protein content was 6.5 gm per 100 cc. In only 4 cases, or 16 per cent, was the total protein content less than 6 gm. In 32 cases in which the hyperthyroidism was of sufficient severity to require a hemithyroidectomy as the first operation, the average value for total serum protein was 6.2 gm per 100 cc., in 11 of these cases, or 34 per cent, the total serum-protein content was less than 6 gm. Again, of the 15 cases in which the total protein content was less than 6 gm, hemithyroidectomy was done in 73 per cent. This indicates a direct relation between the clinical severity of the hyperthyroidism and the level of the total serum protein.

In 5 cases (Table 1, Cases 23 and 30, Table 2, Cases 1, 17 and 26) the serum-albumin content was 3 gm or less, the lowest total being 2.6 gm. Primary hyperthyroidism was present in 4 cases, adenomatous goiter with hyperthyroidism in 1, and in all 5 cases two operations were performed. The average basal metabolic rate in these cases was plus 61 per cent, plus 44 was the average for the entire series. The average values for total serum

protein, serum globulin and the albumin-globulin ratio were 5.9 gm, 3.1 gm and 0.9, respectively. This lowering in the serum-albumin content with slight elevation of the level for serum globulin and reduction of the albumin-globulin ratio indicates what a marked alteration may occur in the serum-protein content in cases in which severe grades of hyperthyroidism are present.

SUMMARY

Analysis of the data presented indicates that marked alterations occur in the serum-protein content of cases with clinical hyperthyroidism. In this series the average value for total serum protein was 6.4 gm per 100 cc on admission to the hospital, in 63 per cent of the cases the determinations were below the normal range. Improvement occurred after ten days of preoperative treatment, when the determinations were below normal in only 37 per cent. Three months after operation in all cases the value for the total serum protein was normal. The serum-albumin content in 73 per cent of cases was below normal on admission, the average being 3.4 gm. Preoperatively, the serum-albumin content was below normal in 53 per cent, with an average of 3.8 gm, and in all cases it was normal three months after operation. No apparent change from normal was noted in the serum-globulin content on admission, and preoperatively the average albumin-globulin ratio was reduced to 1.4, three months after operation it was 2.2, a normal ratio.

No direct relation was found between the level of the serum proteins and duration of hyperthyroidism, basal metabolic rate, amount of weight loss or type of hyperthyroidism. A rough correlation was found between the level of the total serum protein and the excretion of hippuric acid, used as a test of hepatic function.

A relation was found to exist between the level of the total serum protein and the severity of hyperthyroidism, as indicated by clinical opinion as to the need for a one-stage or a two-stage operation. In 73 per cent of the cases in which the value for the total serum proteins was below 6 gm., a two-stage operation was required. Furthermore, in all cases in which the serum-albumin content was 3 gm or less, two-stage operations were required.

The changes noted in the serum proteins may be attributed to disturbances in the function of the liver. Changes in structure and in the function of the liver have been noted in cases of hyperthy-

roidism, and the protein disturbance may be accepted as further evidence of this hepatic change. It is unlikely that the alteration in serum protein is on a nutritional basis, since patients with hyperthyroidism usually eat more food of all kinds than do normal individuals. In hyperthyroidism an increase in the blood volume is found, this being attributed to an increase in the body's need for oxygen. Such a change might be said to produce the lowering of the serum proteins, but this does not seem likely inasmuch as there are parallel increases in both the plasma and cells, as evidenced by normal hematocrit values.

This deviation of serum-protein content from normal may have physiological effects on the body as a whole. It may be responsible for the edema in cases of hyperthyroidism that is not caused by cardiac or renal insufficiency, since in some of these cases the total serum-protein content fell below the critical level. There is a possible relation between serum-protein content and postoperative thyroid crisis.

On the basis of the changes in the values for serum proteins in hyperthyroidism, a part of the preoperative treatment of this disease should perhaps be a high-protein diet. It is admitted that failure has been reported in attempts to alter the serum proteins in cases of cirrhosis of the liver by giving a diet high in protein, in hyperthyroidism, however, a functional rather than a fixed pathologic condition exists, as is evidenced by a return to normal in the serum proteins three months after operation.

A CASE OF HEMOCHROMATOSIS WITH DEGENERATION OF THE HEART MUSCLE AND DEATH FROM CONGESTIVE HEART FAILURE

GEORGE BLUMER, M.D.,* AND ROBERT R. NESBIT, M.D.†

NEW HAVEN, CONNECTICUT

THE peculiar disturbance of pigmentary metabolism known as hemochromatosis usually gives rise to the clinical picture of bronzed diabetes with hepatic cirrhosis, because the process affects preponderantly the pancreas, liver and skin. While the heart muscle is involved in the process in 50 per cent of the cases, and while in many of these there is undoubtedly a certain amount of damage to the cardiac musculature, only rarely is this damage sufficient to lead to pronounced cardiac failure. In the case here presented this complication did occur. The patient was on the service of Dr. William F. Collins, to whom we are indebted for the opportunity to examine the patient and report the case.

CASE REPORT

J. C. B., a retired plumbing contractor 54 years of age, a widower and a native of the United States, was admitted to Hospital of St. Raphael, January 7, 1937. His chief complaint on entrance was cough, and swelling of the entire body. He had been in fairly good health until about a year before admission. At this time he developed a short, nonproductive cough which was especially bad at night. About 9 weeks before admission this cough became worse, though still nonproductive, and sleeplessness and orthopnea developed. There was some substernal pain, which disturbed the patient but was never very severe. About 8 weeks before admission swelling of the feet and ankles was noted, this gradually spread until it involved the subcutaneous tissue of the entire body. During this time the urine was scanty, but the patient had no dysuria or hematuria. He had had no indigestion, and the bowels were normal. There was no loss of weight. For the preceding 2 years he had noticed a scaly condition of the skin, with brownish discoloration.

There was nothing significant in the family history except that the patient's father died at 72 of acute cardiac failure. His earlier history was noncontributory. He was at one time a plumber, but for many years had been a plumbing contractor, so that lead poisoning was improbable, there was no history of exposure to copper. He had been unusually healthy most of his life.

Physical examination showed a well-developed man. The face was puffy, and there was generalized edema all over the surface of the body. The breath was urinous. The tonsils were atrophic. The tongue was clean and moist. There was dullness to flatness at the bases of both lungs posteriorly, especially on the right side, with absence of tactile and vocal fremitus. Moist rales were heard over the upper parts of both lungs. The heart appeared to be somewhat enlarged to the left. The sounds were of only fair quality, there was a systolic murmur

with its maximum over the lower end of the sternum, which was heard also along the right sternal margin. The blood pressure was 132/102. The abdomen was protuberant, there was dullness in the flanks, and the abdominal organs could not be palpated. There was moderate pitting edema of the extremities. The skin was dry and showed a bronzed pigmentation.

Dr. Collins's note on January 6, the day before admission, confirmed these findings. He noted that the patient was apathetic, that the thyroid appeared to be slightly enlarged, that the heart was considerably enlarged and the sounds rather feeble, that the abdomen was tender, especially in the right upper quadrant and that the skin was dry, scaly and deeply pigmented. At this time 400 cc. of clear fluid was removed from the right chest.

On January 19 the patient was seen by one of us (G. B.) in consultation. It was noted that there was pigmentation of the skin involving the entire trunk, the arms, face and legs, especially the upper part of the thighs. The pigmentation was brown but was not uniform. There were areas of less pigmented skin scattered over the body between areas of more deeply pigmented skin. There were small patches of slightly pigmented mucous membrane on the inner aspects of both cheeks. There was marked gingivitis, but no lead or bismuth line. The neck veins were prominent, there was cyanosis of the ears and lips, there were signs of fluid in both pleural cavities, and there was a fair amount of moisture at the lower parts of both lungs. The cardiac impulse was feeble, diffuse and in the fifth space, 9.5 cm. to the left of the median line. The first sound was of poor quality and the sounds at the base were very feeble. The pulse was regular in rate but was small and easily compressible. The abdomen was distended and dull in the flanks, and the abdominal organs could not be palpated on account of this distention. There was marked edema of the genitalia, and marked pitting edema of the legs and thighs. The patient had no fever.

The urine had a specific gravity of 1.020, it contained a slight trace of albumin and of sugar, but microscopically only urates. The basal metabolic rate was -23 per cent. The hemoglobin varied from 80 per cent on admission to 70 per cent, 10 days later. The red-blood-cell count was 5,000,000 on admission and fell to 4,400,000, 10 days later. The leukocytes numbered 12,800 on admission and 18,600, 10 days later, with polymorphonuclears 75 and 81 per cent respectively, the remaining cells being lymphocytes. The fluid from the chest showed no organisms, smears and cultures were negative. The nonprotein nitrogen on two occasions was 48 mg. per cent. The blood Kahn reaction was negative. The blood sugar was 140 mg. per cent on admission, and 200 mg. 10 days later.

The patient gradually failed, and died on January 30.

It was noted that the main difficulty was circulatory, that the man was suffering from pronounced congestive heart failure, which did not respond to ordinary methods of treatment, and that the history of substernal pain suggested the possibility of coronary-artery disease. It was thought that the congestive failure was caused by arteriosclerotic heart disease. This diagnosis did not of course explain the pigmentation, in the discussion of this

*From the Medical and Pathological services of the Hospital of St. Raphael, New Haven, Connecticut.

†Consulting physician, Hospital of St. Raphael.

†Pathologist, Hospital of St. Raphael.

it was pointed out that the blood pressure made the diagnosis of Addison's disease extremely unlikely, and that a diagnosis of hemochromatosis was indicated, especially in view of the trace of sugar in the urine and the high blood sugar content.

The autopsy was performed by one of us (R. R. N.) on January 30. The important anatomical diagnoses and the chief items of interest in the gross and microscopic examinations of the organs mainly affected by the disease follow.

"Anatomical Diagnoses hemochromatosis of the spleen, pancreas, liver, skin, thyroid gland and lymph nodes, hemochromatosis of the heart with marked fibrosis, cirrhosis of the spleen and liver, cardiac mural thrombi, acute pulmonary and visceral congestion with pulmonary hemorrhage, pericardial and bilateral pleural effusion, ascites, generalized pitting edema, chronic passive congestion of the viscera, early arteriosclerosis.

'The heart weighs 410 gm. The pericardial surface is

Heart Muscle (enlarged from 400 X, G and H filters, phosphotungstic acid and hematoxylin stain) The pigment infiltration, the fractionating of myofibrils and connective-tissue proliferation are shown. In the outer edges, on either side, are shown fibrils which still retain some of their cross striations although the pigment granules are seen within the fibrils, in the center the complete replacement of fibrils by pigment and their massive destruction are well demonstrated.

smooth. There is a very noticeable brown pigmentation. The coronary arteries are moderately thickened, but there are no demonstrable occlusions. The coronary veins are congested and dilated. The myocardium is rather soft and flabby. On section, the myocardium is deep-brown and shows intense streaking and scarring, also noticeably brown. The right side of the heart is markedly dilated. In the right auricular appendage is a large, well-organized, adherent gray-red clot. There is a similar clot in the left auricular appendage. The remainder of the endocardium is smooth, and the valves are all free and appear functionally normal. No vegetations are demonstrable.

Microscopic examination shows that the epicardial fat is normal. The coronary arteries show a slight intimal proliferation without any medial changes, no vessel can be found in any section which is appreciably diminished in caliber. The myocardium is characterized by an intense pigment infiltration of the myofibrils, with degeneration and replacement fibrosis. This pigment gives a positive iron reaction. The myofibrils show varying degrees of degeneration, some with slight loss of cross

striations and varying degrees of pyknosis of the nuclei, others with marked fragmentation and dropped nuclei, while practically all show some degree of irregularity of staining. In some instances large deposits of pigment are laid down in lines, apparently within the sheath of the fibrils, while in other foci clumps of pigment granules lie within a fibroblastic mesh, in which may be seen occasional mononuclear phagocytes containing engulfed pigment. The endocardium of the auricle and the auricular appendage is covered by a thrombus, some of which is organized and shows fibroblastic proliferation, while the remainder shows a more recent process in which fairly well preserved erythrocytes are still visible, as compared to the almost completely degenerated cells in the older portions. The veins throughout the sections are intensely dilated by closely packed red cells.

'The spleen weighs 210 gm. The capsule is smooth and dark. The organ is very firm, and on section imparts a gritty feeling through the knife. The cut surface is purplish red, due to congestion, and shows apparent increase of fibrous stroma.

'Microscopic examination shows nothing of note in the capsule. The sinusoids are widely distended by red cells and many mononuclear phagocytes containing engulfed debris and pigment. The endothelial lining cells are in almost all instances loaded with iron-positive pigment, so that some of these cells appear triple their normal size. The lymphoid follicles are obscured by the intense congestion, but otherwise are normal. The arteries show a slight intimal proliferation, more marked than that observed in the heart. The veins are intensely engorged with red cells.

'The pancreas weighs 130 gm. It is a deep mahogany brown. It is firm, and on section this color is present throughout its entire structure. There is no evidence of hemorrhage.

'Microscopic examination shows that the sections of pancreas are essentially brown. Almost all the acinar cells and those of the islets are filled with iron-positive pigment, and the whole islets and large groups of acinar cells are completely degenerated with pyknotic or dropped nuclei. Between the lobules and also in the intra-acinar spaces there is a marked fatty infiltration throughout the sections, while others show focal fibroblastic proliferation replacing portions of the lobules. In this tissue are numerous mononuclear phagocytes with engulfed pigment, and also clumps of pigment, lying free. The islets throughout are seen to be more seriously involved by the pigment infiltration than are the acinar cells. The ducts of the pancreas show desquamation of epithelium, but are otherwise normal. The arteries show a moderate intimal proliferation, and the veins are intensely engorged with red cells.

'The liver weighs 2150 gm. The capsule is smooth but irregular, because of changes in the hepatic structures beneath. The organ is intensely brown. On section, a definite gritty feeling is imparted through the knife. A large amount of dark blood oozes from the cut surface. When this is scraped away, an increase of intense brown fibrous tissue is seen, and the hepatic tissue is markedly diminished and is a very deep brown. This increase in fibrous tissue appears to outline the periphery of the lobules of the liver. The veins are markedly congested and dilated. Grossly, the biliary system and gall bladder are not remarkable.

'Microscopic examination shows that the sections, like those of the pancreas, are mainly brown. There is an intense peripheral fibroblastic proliferation, in which there is evidence of bile duct proliferation. The fibrous tissue

and the bile-duct cells are both loaded with iron-containing pigment which, in the fibrous tissue, is present in free clumps and also in the mononuclear phagocytes. The bile-duct cells show marked degeneration with pyknotic and dropped nuclei as a result of the pigment infiltration. The fibrous tissue contains isolated small groups of parenchymal cells, which are likewise loaded with pigment. The parenchymal cells almost without exception contain varying amounts of pigment infiltration. In some instances there are whole clumps of cells in which nuclei are not demonstrable, or else are pyknotic. The cytoplasm is very coarsely granular and stains irregularly. The sinusoids are widely dilated and filled with closely packed red cells, and the central veins show similar processes. The Kupffer cells in many instances show marked phagocytosis of pigment.

"All the lymph nodes examined, including those of the mediastinum, the upper and lower abdomen and the pelvis, are enlarged and very deep brown. The brown color is universally distributed through their substance. The nodes of the mediastinum are much more markedly swollen than those elsewhere, and are soft and boggy.

"Microscopic examination shows an intense iron-containing pigmentation, the pigment lying free or in the cytoplasm of phagocytes which fill the sinusoids. There is moderate hyperplasia of the lymphoid follicles.

The thyroid is a very deep brown, and on section this color is distributed throughout the gland. The colloid is diminished, and the gland is small and contracted. There is apparently an increase in the fibrous tissue.

"Microscopic examination shows an intense pigmentation of the acinar cells with varying degrees of degeneration, but complete in numerous instances. Entire alveoli are frequently replaced by cell membranes containing large clumps of iron positive pigment. There is a marked proliferation of fibroblasts surrounding the alveoli, and in this fibroblastic tissue there is a very prominent lymphoid infiltration. Large numbers of mononuclear phagocytes filled with pigment are seen. The colloid is greatly reduced in amount.

DISCUSSION

Involvement of the heart muscle in hemochromatosis is by no means uncommon. Bork,¹ in his study of the pathology of the disease, states that in practically all his autopsies there was found considerable pigmentation in the muscle fibers of the heart. Sheldon² states that the heart muscle is pigmented in at least 90 per cent of the cases, the pigment often being present in huge amounts. Blanton and Healy,³ in their review of 22 cases, state that a half showed hemochromatosis within the heart muscle, and that the pigment was generally situated intracellularly at the nuclear poles, fibrosis of the heart muscle was found only once, and was not of marked degree. It is evident from these reports that pigmentary deposits in the cardiac muscle are very frequent but that they seldom lead to marked fibrotic changes.

So far as the case under consideration is concerned, it will be noted that there was very extensive pigmentary deposit and that this was associated with extensive fibrosis of the heart muscle. Furthermore, although the patient had suffered from substernal pain during life, the gross and

microscopic examination of the heart showed almost normal coronary vessels. It would therefore seem logical to assume that the fibrosis in this case was associated with the pigmentary deposit.

It is necessary however to discuss one other possibility: there is a group of cases of hemochromatosis which have been described, particularly by French authorities, in which cardiac failure, probably of a different origin, is a prominent feature. We refer to the syndrome described by Clerc, Bascourret and Andre,⁴ by de Gennès, Delarue and de Vericourt⁵ and by Bezançon, de Gennes, Delarue and Oumansky,⁶ which is characterized by the association of hemochromatosis with infantilism and cardiac failure. This syndrome is described as pigmentary cirrhosis with infantilism, cardiac insufficiency and multiple endocrine aplasia, or as the "endocrinohepatocardiac" syndrome. The essential features of this syndrome are (1) its occurrence at an age which is definitely below the average of most patients with hemochromatosis, (2) an involvement of the endocrine glands, particularly the testes which are atrophic, (3) the occurrence of infantilism as part of the syndrome, and (4) death from cardiac failure. Judging from the description of the French writers the origin of the cardiac failure in these patients is not in the heart muscle itself, because the pathologic changes in the heart muscle are often not particularly pronounced, but is to be explained on an endocrine basis. De Gennes, Delarue and de Vericourt⁵ speak of the condition as a true polyglandular syndrome. They mention the fact already commented on, that although there is evidence of hemochromatosis of the myocardium in most autopsied patients, cardiac insufficiency is rare. They discuss the different types of cardiac failure of endocrine origin, and point out that Waller has described cardiac failure caused by ovarian insufficiency, and that the cardiac insufficiency of thyrotoxicosis and that caused by thyroid insufficiency are well known. They also speak of the role of the adrenals in the production of cardiac insufficiency, the circulatory failure of Addison's disease being a well known example of this condition. They conclude that in this particular group of cases the cardiac failure is of endocrine origin rather than caused by the pigmentary changes in the heart muscle. As a matter of fact, Bezançon and his co-workers⁶ had put forward this same explanation two or three years earlier.

In the case under discussion—a well-developed male of fifty-four—there was no evidence of infantilism, and the autopsy did not indicate any extensive degeneration of the endocrine system except for the pancreas and, to a lesser extent, the thyroid gland. Even in the pancreas fairly normal islands of Langerhans often stood out in the midst

of areas of connective tissue, and while the patient had a high blood sugar, only a trace of sugar was present in the urine and the usual picture of pronounced diabetes was lacking. There was no evidence of testicular atrophy.

CONCLUSIONS

1 The heart muscle is the site of pigmentary infiltration in a large proportion of patients with hemochromatosis.

2 This pigmentary deposit seldom leads to extensive interstitial myocarditis.

3 Occasionally, as in the case reported, interstitial changes occur, and these may be so wide-

spread that they are capable of causing fatal congestive heart failure.

NEWER DRUGS FOR THE TREATMENT OF TAPEWORM INFESTATIONS

Some Results Obtained With Carbon Tetrachloride, Tetrachlorethylene and Hexylresorcinol

J H SANDGROUND, D.Sc *

BOSTON

IN CONSIDERING the essential merits of any anthelmintic, two questions always present themselves: the first concerns its potential toxicity for the host, the second has to do with its efficacy in eliminating the parasite. Other questions also arise, but these are for the most part ancillary.

Among the many medicaments of plant origin which through the centuries have been prescribed for the elimination of tapeworms from man, the drug derived from male fern (*Aspidium* spp.) still enjoys the greatest vogue. The powdered rhizome of the fern, mixed with various other substances, is mentioned by Galen, Pliny and other classical writers. But because treatments often and for unknown reasons fail, efforts to isolate the active principle, filicin, have led to the use, in more recent times, of various extracts of the roots, sometimes in combination with powdered acacia.

As a matter of course, few physicians hesitate to use male fern, for it is the drug most generally recommended in textbooks and treatises on therapeutics. In a recent article, Faust¹ states that "the most reliable drug for all tapeworm infections is probably oleoresin of aspidium." Its potential toxicity, however, must always be kept in mind. The literature is replete with records of severe toxic sequelae, such as headache, vertigo, dyspnea and cyanosis. It often produces gastritis. When absorbed into the system it damages the kidneys and may affect the central nervous system, leading

to various optic disturbances, delirium and stupor. An appreciable number of fatalities following the administration of male fern have also been reported. Contraindications do not appear to be well defined, but some of the conditions in which the drug is to be avoided include pregnancy, in fancy and old age, anemia, and debility due to chronic disease or acute infection.

Treatment with male fern calls for caution and is always time-consuming. To render it effective the patient's diet should be limited to liquids for at least twenty-four hours, and there should be thorough purgation before treatment is instituted. The drug is intensely bitter, and usually produces nausea and vomiting. In order to control toxicity, therefore, as well as to ensure retention of at least part of the medicine, the dose is often given in two or three gelatin capsules at half-hourly intervals. To avoid emesis several recent writers have strongly recommended administration by transduodenal tube, an elaborate procedure, and a discomfiting one for the patient.² That male fern is highly efficacious when it has been freshly extracted, assuring high potency, and when the patient, through attention to diet and to preliminary purgation, has been properly prepared for treatment, is not to be gainsaid (Magath and Brown³). But it is equally true that the results obtained with this drug are exceedingly erratic, even when the patient is hospitalized to secure optimum conditions for treatment.

Another widely used vegetal principle for tape-

From the Department of Tropical Medicine, Harvard Medical School, Boston.
Assistant professor of helminthology, Harvard Medical School.

worm treatment is pelletierine, a mixture of alkaloids extracted from the bark of the pomegranate (*Punica granatum*). The relatively insoluble and more stable sulfate of pelletierine with tannin is said to be the least toxic and most efficacious of the several forms in which the drug is available. Nevertheless, it leaves much to be desired. In any of its forms, pelletierine is very disagreeable to take and is liable to produce nausea, vomiting, and in large doses, cerebral symptoms. Again effectiveness is dependent on preparing of the patient by restricting the diet for a day or two and by rigorous purging before and after treatment.

Pelletierine is usually prescribed after failure with male fern. However, as many of the patients seen by us attest, even Tanret's pelletierine, a highly lauded and expensive proprietary product often fails to achieve its purpose. The majority of our patients in Boston give a history of from one to several unsuccessful treatments with either male fern or pelletierine or both, and not a few were discouraged at the prospect of getting rid of their insidious guest. An extreme commentary on the unreliability of standard tapeworm remedies is found in the *British Medical Journal*, where a correspondent⁴ tells of failing repeatedly to depurate a patient, and of finally resorting to operation, at which *the worm was expelled by flushing the intestine with 1 per cent iodine solution*¹.

A proper evaluation of male fern or pelletierine as taeniocides and as drugs liable to produce serious toxic sequelae or fatalities is impossible for lack of statistics, but they obviously do not approach the standards attained by a number of anthelmintics that have been latterly introduced for the treatment of other helminth infestations. Progress in this branch of therapy has now reached the point where, for several species of worms, a choice of highly effective drugs is available and the ideal method of treatment is actually envisaged. This ideal anthelmintic has been defined in terms of absolute safety for the patient and the complete absence of contraindications to its use. It must be easy to administer and not unpleasant to take. Where large masses of people are in need of treatment, the drug should be cheap and easily obtainable in a pure form, and should possess a high order of efficacy. Safety for the patient is naturally a prime requirement of any drug. Where tapeworm infestations are involved, only rarely can the parasite be charged with such pathogenic potentialities as to warrant taking measures for its expulsion which may jeopardize the patient's life.

As might be expected, the perfect taeniocide is still to be discovered. Starting with an unexpected demonstration of the efficacy of carbon tetrachloride in a case of *Taenia solium* infestation, dur-

ing the past eight years we have sought to evaluate this and two other drugs that have less objectionable features than the remedies now commonly employed. Despite unremitting efforts, however, we have been able to outline the course of treatment in only 38 cases. Though this series is too small to warrant final conclusions, our results may be of interest and may serve as a guide to the practitioner.

The number of species of tapeworm that normally may affect man is small, and so far as present information indicates, all these species yield to the same drugs in a nonspecific manner. By far the commonest species of tapeworm involved in our cases from the Boston region was *T. saginata* whose infectious cysticercus stage occurs in beef. *T. solium*, the armed or hooked tapeworm of porcine origin, is veritably nonexistent in this region, and is a rarity in most countries with enlightened systems of meat inspection. Our experience with this species is represented by 3 cases which we treated under primitive field conditions in Yucatan and South Africa. Included in our Boston series also are 5 cases of infestation with *Diphyllobothrium latum*, the broad fish tapeworm which is occasionally encountered among the foreign born members of the community especially those coming from regions bordering on the Baltic Sea.

BIOLOGICAL FACTORS IN RELATION TO PROBLEMS OF TREATMENT

From the zoological viewpoint, a tapeworm represents a self-perpetuating colony of organisms (the segments or proglottids) each of which autonomously performs the functions of food assimilation and sexual reproduction. The head (scolex) with its suckers is the organ with which the entire chain or strobila of segments secures a hold on the wall of the small intestine, usually the lower duodenum. Tapeworms increase in length by budding off new segments. The zone of proliferation is in the neck region, immediately behind the scolex. As the terminal segments mature and become gravid, they spontaneously detach themselves and are passed out singly or in short rows. It is by the passage of segments that infections are usually diagnosed, this being done more often by the patient than by the physician or laboratory worker. For several reasons the microscopic search of the feces for eggs is not a reliable index of infestation. When the parasite is subjected to the influence of irritating drugs and other adverse conditions the longitudinal muscle fibers that hold the segments together may rupture at any point. But unless the scolex is rendered nonviable regeneration will eventually occur. Consequently the expulsion of the scolex furnishes the only immediate

evidence of a final or complete cure. Yet several hours may elapse after treatment before peristalsis delivers the parasite. In this event it often happens that the chain is broken into numerous segments and fragments, variable in size and appearance. The scolex may well be among these isolated scraps, but to find it involves a tedious as well as odious washing of the feces through sieves. In addition, it requires an ability to recognize the scolex that is not often possessed by the non-specialist.

Thus, failure to identify the scolex does not necessarily mean that it has not been expelled or that treatment should be repeated. In any event, the patient should be spared a second treatment until some time has elapsed, for the toxic effect of most anthelmintics is cumulative. In cases where the scolex has not been recovered, the passage of sufficient time for regeneration of the strobila becomes the critical test of cure. Therefore, in order to assess the efficacy of the drug it is necessary to keep a check on the patient for a considerable period, during which he must observe every precaution against reinfection.

The potential longevity or natural life span of these parasites is reliably known to be not less than from twenty to thirty-five years. Hence natural death of the parasite and spontaneous cure of the patient are hardly likely to occur within the ordinary period of observation. The essential question is, How long must be the period of absence of signs of infestation before the test treatment can be accounted successful? In the majority of unsuccessful treatments with male fern, segments reappear in the stools within six weeks. Insofar as experimental studies have shown that the species of tapeworms here considered come to maturity and release segments within sixty to seventy-five days after the infectious larval stages have been ingested, from ninety to one hundred days has been regarded as a conservative period of probation by the few investigators who have considered this factor in evaluating results.⁵ As our results have shown, this period of freedom from passing segments does not afford a reliable index of the taeniocidal value of all drugs, for we have had several cases treated with hexylresorcinol who claim to have been free from segments for as long as eight months before recidivism became manifest. In these cases the possibility of a renewal of the infestation cannot, of course, be entirely excluded, but it seems highly improbable, for even were larval infestation of beef less rare than it is, our patients have been so worried by their infestations that they have needed no urging in order to adopt the strictest dietary precautions.

CARBON TETRACHLORIDE

Before presenting our own observations, it will be well to review briefly the history of carbon tetrachloride as an anthelmintic, pointing out some of the virtues of the drug as well as its shortcomings.

Before the inauguration of a formal project for the standardization and development of new anthelmintics by the Bureau of Animal Industry of the United States Department of Agriculture, the attitude toward anthelmintic medication was one of uncritical empiricism. As a result of a series of critical experiments in 1921, Hall⁶ discovered that carbon tetrachloride (CCl_4) was an excellent remedy for canine ancylostomiasis, and recommended the trial of the drug as an anthelmintic for man. This suggestion was almost immediately acted upon, but before the drug became widely adopted as a specific against hookworm, exhaustive tests were carried out on many subjects, including criminals who were about to be executed.⁷ At first, carbon tetrachloride appeared to be completely lacking in toxicity. Within a few years of its introduction it had been administered to millions of people in tropical and subtropical countries, where, on the score of its general safety and relative cheapness, it has become the drug of choice for the treatment of ancylostomiasis. Used with ordinary discretion it gives admirable results, as indicated by Lambert,⁸ who has reported 100,000 treatments for hookworm among the natives of the South Pacific islands, without a single death and with few untoward sequelae. In Egypt, where 5 cc. is the routine dose for adults, Tomb and Helmy⁹ have recently reviewed the question of the toxicity of carbon tetrachloride on the basis of the treatment of 1,600,000 patients. Nineteen fatalities were recorded, but the majority of these, it is claimed, could have been prevented. The occurrence of occasional fatalities has led to a comprehensive investigation of the pharmacology of this compound.¹⁰

Because of its remarkable record of safety in an enormous number of cases, carbon tetrachloride must be recognized as one of the most valuable drugs in the entire pharmacopoeia. Yet any notion that it is innocuous has been dispelled. To some extent it is always absorbed into the system, and damage, particularly to the liver parenchyma, consistently follows, even though the patient may show no clinically recognizable symptoms. To reduce absorption from the intestine, an effective saline purge (preferably sodium sulfate) should be administered either with the anthelmintic or within an hour after taking it. All liquids containing alcohol, and all foods rich in fats, both of which tend to enhance absorption, should be enjoined.

for at least a day before and after treatment. It is imperative that there be prompt purgation within a few hours, and in cases of stubborn constipation, enemas or other methods of procuring elimination must be used.

In this connection a note of warning is necessary, the opinion having been expressed that some of the deaths following carbon tetrachloride have been due to too vigorous purgation with saturated magnesium sulfate solution rather than to the poisonous action of the drug. Chronic or acute cirrhosis, whether due to alcoholism or to other causes, and kidney disease are mentioned as the outstanding contraindications to the exhibition of carbon tetrachloride; the drug should be combined with oil of chenopodium in cases where round worms (*Ascaris lumbricoides*) are also harbored. To minimize the effect on the liver, it is advised that the blood-calcium reserve be built up and that carbohydrates in the diet, particularly sugar, be increased for some days before treatment. A certain amount of nausea, dizziness or headache is to be expected, but the patient should not be alarmed, for these symptoms usually disappear as soon as the bowels move.

In some cases, deaths following the administration of carbon tetrachloride have been ascribed to an idiosyncrasy. Furthermore, toxicity does not appear to bear a direct relation to the dosage. On occasion, but apparently unintentionally, as much as 50 cc.—which is almost ten times the usual dose—has been administered without evoking serious symptoms of intoxication.¹¹ On the other hand, deaths have been recorded following the taking of as little as 1.5 cc. It is well to remember, however, that in extended series of treatments given under field conditions, where physical examination is necessarily omitted, the death rate is probably no higher than 1 per 100,000. Most of our patients were well-nourished adults, but we have never found it necessary to give more than 4 cc. In the case of an aged and rather debilitated woman, 3 cc. was given, and in the case of a boy of twelve caution suggested that only 2 cc. be administered.* The drug, given either in water or with a little milk, has always been well tolerated, although there is usually some dizziness and drowsiness during the first hour. As our results bear witness, for effective treatment against tapeworm it is not at all necessary that the patient be starved before treatment or that there be a preliminary purgation, but on general principles patients have been advised to restrict their supper to toast and milk, and to have an enema on the evening before taking treatment. The drug is given the first thing in the morning, the patient refraining

from eating until good purgation has occurred. The tapeworm is usually expelled within two or three hours after treatment, and thereafter the patient may resume normal activity.

Deriving their opinion by analogy from the results of therapeutic tests with tapeworm-infested dogs, Hall and Shillinger¹² at first declared that carbon tetrachloride was probably of little value against tapeworms in man or in other animals, Chandler and Mukerji,¹³ working in India, concurred. It is interesting to observe that these early opinions, based as they must have been upon personal impression rather than upon tests, were completely reversed within a few years.

Attention was first called to the value of carbon tetrachloride as a specific against the tapeworms of man by Daubney and Carman,¹⁴ who while treating hookworm patients in East Africa in 1928 noticed that after the administration of a mixture of carbon tetrachloride and oil of chenopodium tapeworms were often passed. The incidence of *T. saginata* among these raw meat-eating natives is extremely high, and provides ample opportunity for testing taeniocidal drugs. On testing the effect of 4 cc. of carbon tetrachloride on 30 patients, Daubney and Carman found that after a lapse of seven weeks only 1 patient was still passing tapeworm segments, a therapeutic efficiency of 97 per cent. Two interesting and rather significant observations derived from further tests were these: (1) the efficacy of the drug appeared to be reduced rather than enhanced by subjecting the patient to preliminary catharsis, (2) the tapeworm was usually dead on expulsion and had undergone fragmentation, so that the scolex was rarely found attached.

Other investigators have shown that a detached scolex undergoes rapid degeneration, so that it can scarcely be recognized when found in the feces. Continuing studies on the treatment of tapeworm infestations in Kenya Colony, Carman¹⁵ recorded comparably favorable results in from 2500 to 3000 natives who were given a mixture of 4 cc. carbon tetrachloride and 1 cc. oil of chenopodium.* The treatments were given on an outpatient basis at field posts, without a single instance of untoward symptoms. Similarly enthusiastic reports on the efficacy of carbon tetrachloride as a convenient and effective drug for the removal of *T. saginata* have recently appeared in the literature of many countries, for example, Kemp,¹⁶ Hoffman¹⁷ and Talice.¹⁸

The first 4 patients in the series presented in Table 1 applied for treatment in the field while

*Although it has long been known that oil of chenopodium is by itself often capable of expelling tapeworms, the investigations of Napleton and Mukerji¹³ have shown that the carbon tetrachloride in the mixture here mentioned is the more effective of the two.

For young children, Lambert¹⁹ prescribes 0.2 cc. for each year of age.

we were on expeditions in Yucatan and Rhodesia, where, without facilities for accommodating the patient, it was impractical to continue observation for more than two hours. Within this period, in 2 of these 4 cases we were able to confirm the expulsion of the worms with scolices attached, in the other 2, final assessment of efficacy could not be made. The remaining 12 cases, including 2 cases of *D. latum* infestation, were treated in or near Boston, either in hospitals or in the patient's home under the care of the family physician. In Case 33

Table 1 *Results of Treatment with Carbon Tetrachloride*

CASE NO	SPECIES	DOSE	RESULTS OF FOLLOW UP	
		cc		
1	<i>T. solium</i>	4	Worm passed up to neck	No follow up
2	<i>T. solium</i> and <i>T. saginata</i>	4	Three worms passed two with scolex	
3	<i>T. saginata</i>	4	Worm passed with scolex	
4	<i>T. saginata</i>	3	Worm passed in fragments	No follow up
5	<i>D. latum</i>	4	Scolex passed	
6	<i>T. saginata</i>	4	Worm passed up to neck	No later report from patient
7	<i>T. saginata</i>	4	Worm passed in fragments	Patient free from segments after 28 months
11	<i>T. saginata</i>	4	Two worms passed with scolex	
16	<i>T. saginata</i>	4	Treatment at home.	Patient free from segments after 18 months
27	<i>T. saginata</i>	4	Worm passed with scolex.	
28	<i>D. latum</i>	4	Worm in fragments (with scolex?)	Patient free from segments after 10 months
30	<i>T. saginata</i>	4	Worm passed with scolex	
33	<i>T. saginata</i>	4	Drug vomited on two occasions	No cure
34	<i>T. saginata</i>	2	Worm passed with scolex	
36	<i>T. saginata</i>	4	Worm passed with scolex	
38	<i>T. saginata</i>	4	Worm passed in fragments	Patient free from segments after 10 months

the hospital intern reported that the patient could not tolerate the drug and vomited each time it was given. Although several feet of the worm chain were passed, this case is reckoned as a failure, but it might justifiably have been excluded from the series. Of the remaining 11 cases, reports subsequent to treatment were secured in all but 1 (Case 6), and although search for the scolex was futile in several cases, the statements of the patients indicated that treatment was completely satisfactory. These results are very much in keeping with the favorable reports to which reference has already been made.

TETRACHLORETHYLENE

Like carbon tetrachloride, tetrachlorethylene (C_2Cl_4) was also introduced into medicine via the veterinary field. Before its trial in human beings was suggested, Hall and Shillinger²⁰ had found the drug to be almost as efficacious against hookworm in the dog as was carbon tetrachloride, over which it appeared to have two advantages: it had a less unpleasant taste, and, being less soluble in water, it was less readily absorbed through the intestine, so that it produced no detectable pathologic or functional damage to the liver, even when administered together with alcohol to increase

absorption in test animals. Tetrachlorethylene has been given in innumerable cases (probably several hundred thousand) of hookworm infestation without any fatalities, or cases, of serious intoxication being reported. In the literature it is mentioned that occasionally there is vomiting, and slight vertigo of an anesthetic rather than a toxic nature. Although tetrachlorethylene lacks the toxicity of carbon tetrachloride, it is not used on such a massive scale as the latter. This is possibly because of its slightly greater cost, and possibly because of a general conviction that in actual practice the dangers of carbon tetrachloride are negligible.

Because of the reputed superiority from the pharmacologic standpoint of tetrachlorethylene over carbon tetrachloride, we attempted to determine its taeniocidal value. The experience of Hall and Shillinger²⁰ indicated that the drug was of no value against tapeworm in dogs, but it does not appear to have been adequately tested for these infestations in man. In the literature, the only reference that we have found is the brief and incidental mention of Maplestone and Mukerji¹⁹ that they tried tetrachlorethylene (dosage not stated) on three patients with no apparent effect on the tapeworm.

Unfortunately, the number of cases in our series is too small to warrant final conclusions as to the value of tetrachlorethylene against *T. saginata*. Altogether it was tried in 8 cases, the dosage being generally 4 cc and the method of treatment being similar to that with carbon tetrachloride. On each occasion a large portion of the strobila extending up to the attenuated neck region was expelled, but the scolex was never found attached. In 3 cases we received no report from the patient after his discharge from the hospital. In 1 case, segments reappeared twelve days after treatment, while in another they did not reappear until nearly three months had elapsed. The fifth case concerned a patient who was admitted to the hospital with severe jaundice and fever of undiagnosed origin. The only positive laboratory finding was a tapeworm infestation, which the physician considered might have involved the bile duct and caused obstruction. In view of the patient's condition tetrachlorethylene appeared to be the drug of choice, and 3 cc was administered instead of the usual 4 cc. A mass of tapeworm segments was passed in due course, but the scolex was not found. After an exploratory operation a month later, the patient died. At autopsy a large liver abscess, possibly amebic, was found, but the pathologist reported no trace of a tapeworm in the intestine. The conditions presented in this case may be regarded as an ideal set-up for the crucial test of a drug's efficacy. In the 2 remaining cases of this series, according to reports received about six months after

treatment, there was no recurrence of infestation. There consequently appear to have been cures in 3 of the 8 cases treated with tetrachlorethylene.

HEXYLRESORCINOL

Hexylresorcinol was introduced by Leonard¹ in 1924 for the treatment of genito-urinary infections. In preliminary tests, it was taken by Leonard and several volunteers in 1 gm doses, four times a day for two consecutive weeks, without any toxic manifestations. In 1930, Lamson, Ward and Brown² first drew attention to hexylresorcinol as an anthelmintic that was especially effective against *A. lumbricoides* and other nematode parasites in the intestine, and that indeed closely approached the ideal anthelmintic. The drug has been very widely used as a urinary antiseptic, and has been given as an anthelmintic to thousands of persons without serious sequelae.

Hexylresorcinol is soluble in alcohol, glycerin and vegetable oils, but only slightly in water. Because of its affinity for proteins, solutions in olive oil, for example Caprocol, are likely to be inert. For this reason hexylresorcinol is best given as an anthelmintic in the form of sugar-coated pills, on an empty stomach. Lamson et al.²² prescribed doses ranging from 0.15 gm for young children to 10 gm for adults.

Our tests of hexylresorcinol as a taeniocide were initiated early in 1931. In the following year, Lamson and Ward²³ mentioned having rid dogs of tapeworms with this substance and having tried it in several patients who expelled yards of worms without the scolex. More recently, Maplestone and Mukerji²⁴ in Calcutta reported treating 10 cases of *T. saginata* with 1 gm doses of this drug in hard gelatin capsules. Reports from 9 of the 10 patients three months after treatment showed the return of segments in the stools of 4. The authors discontinued their trials of hexylresorcinol on the ground that carbon tetrachloride was cheaper and yielded better results.

In our series of 24 cases, initial tests with hexylresorcinol were made with 1 gm doses of sugar-coated pills†. The following simple procedure was usually adopted. After a light evening meal the intestinal tract was cleared as much as possible without incommoding the patient. The pills were administered on arising next morning, with an unlimited amount of water to reduce or prevent the slight burning sensation in the epigastric region that is sometimes the subject of complaint*. A few of our female patients vomited,—largely

it appears, because of the revival of unpleasant memories associated with previous experiences with male fern,—but the distress appears never to have been severe. A mineral oil or saline purge was given about an hour after the drug and food was withheld for another few hours. Often the parasite was expelled much shriveled and evidently dead. However, since fragments of the chain may continue to pass for at least forty-eight hours we usually dispense with a search for the scolex in the feces. When some of the patients reported remission of segments, we decided to give subsequent treatments with larger doses to all except debilitated subjects. The safety of much larger doses had already been indicated by Leonard's²¹ experiments, and we ourselves did

*Second treatment.

†Given in two equal doses on successive days.

not observe any untoward effect after administering three 1-gm doses of hexylresorcinol at approximately hourly intervals on two consecutive mornings.

As shown in Table 2, hexylresorcinol is to be credited with success in at least 7 out of 24 trials. The medication may be effective in doses as low as 1 gm. On the other hand, a dose of 3 gm given at hourly intervals may fail. Whether or not the method of administration is the factor responsible for the lack of consistency in the results is a question requiring further investigation.

The observation that after exposure to an anthelmintic a tapeworm may not evince signs of its con-

*Supplied through the courtesy of the manufacturers Sharp and Dohme, Philadelphia.

Hexylresorcinol has the qualities of a local irritant, producing a burning sensation with superficial necrosis on the tongue and on the gastric mucosa. Hence children are cautioned against chewing the sugar-coated pills. The irritant effects are usually mild and transient; the damage to the mucosa is rapidly repaired and is clinically negligible.

CASE 24071

PRESENTATION OF CASE

First Admission A thirty-three-year-old, white Canadian housewife entered the hospital with the complaint of abdominal pain of eight days' duration

Eight days before entry she noticed the onset of mild, crampy, low back pain, which during the day became gradually more severe and radiated to both lower quadrants, particularly the right. The patient said the pains resembled labor pains. She had complete anorexia with frequent nausea and would have gone to bed if she had not had to take care of four small children. She also became somewhat constipated, and during the two days before entry her bowels did not move. On the second day of her illness the pain became localized in the right lower quadrant, but two days later it became much more severe and generalized, persisting thus up to the time of entry. She had severe nausea and vomited once on the morning of entry. She had had no previous attacks, but for several months she had been subject to "bilious spells" with headache, nausea and vomiting which lasted one or two days and occurred about every two weeks. For some months she had felt tired and physically below par. She had had no fever or other symptoms except one brief shaking chill on the morning of entry.

Her menstrual periods had always been regular up to one year before entry, when they became prolonged, lasting ten or twelve days, with excessive bleeding and clots. Two months before entry the interval between periods became suddenly shortened to eighteen days, and the menorrhagia persisted. Her last period ended nine days before entry, but two days later she flowed again for a single day.

She was born in Nova Scotia and for the four years before entry had lived in a town near Boston. She had never been anywhere outside of the north eastern part of North America. However, her husband, in the course of his business, periodically received shipments of snails from South Africa which both she and he handled and sorted for distribution to museums and other institutions in this country. Her past history and family history were noncontributory.

Physical examination revealed a well-developed

and nourished, pale, listless female, appearing acutely ill. The heart and lungs were negative, and the blood pressure was 126 systolic, 80 diastolic. There was moderate distention of the lower part of the abdomen, and peristalsis was much diminished. The entire abdomen was tender throughout, with exquisite tenderness and spasm in the right lower quadrant. A very tender grapefruit-sized mass could be palpated in that area, and there was marked rebound tenderness. On pelvic examination a large tender mass could be palpated in the right vault, and the left vault was diffusely tender.

The temperature was 103.6°F by rectum, the pulse 132. The respirations were 24.

The urine examination was negative. The blood showed a red-cell count of 4,000,000 with 60 per cent hemoglobin, and a white-cell count of 26,500. The corrected sedimentation rate of the red cells was 0.1 mm per minute. The nonprotein nitrogen of the blood serum was 19 mg per cent, the protein 4.9 gm per cent, and the chlorides equivalent to 99 cc of N/10 sodium chloride. On the fourth day an operation was performed. An oblique incision was made over the tender mass centered at the right border of the rectus muscle. When the peritoneum was incised, matted coils of intestine presented. The fibrinous adhesions were easily separated, and a large well-walled-off abscess was found, which apparently lay medial to the cecum. It was aspirated, and drainage wicks were placed into it before closing the wound.

Bacteriological examination of the fluid failed to show any organisms. Two days after the operation her temperature had fallen to normal, and her white-cell count gradually fell to 7700. Over a period of three weeks the wound continued to drain pus which slowly lessened in amount. A culture of the pus on the eleventh postoperative day showed *Staphylococcus aureus*. She was discharged on the twenty-eighth day, at which time no masses could be made out in the abdomen. However, pelvic examination showed definite thickening and induration in the right vault.

Final Admission (five weeks later) After discharge she went to a convalescent home where she stayed up to the time of re-entry. The wound continued to drain moderate amounts of semi-fluid, green, non-odorous material without any blood or feces. She had a slight dull ache in the region of the sinus, but no severe pain. Her appetite was good and she gained 13 lb in weight. Her bowel movements were normal.

Physical examination showed the right lower-quadrant scar with a draining sinus. There was some tenderness and spasm in the surrounding area, and pelvic examination showed induration and tenderness in the right vault.

give pain in the left side as well as the right, but there again, if a Meckel's diverticulum were inflamed and formed an abscess, one would expect to find *Bacillus coli* in the original drainage of the abscess and, again, that the sinus tract would heal or form a fecal fistula. It is possible that perforation of the intestine into the mesenteric border by foreign body, such as a porcupine quill or needle, might have caused a sterile abscess in the mesentery which could give such a picture as this, and if the foreign body did not come out in five weeks, I suppose it is possible that it might keep the tract open. But there is no history suggesting such a possibility, and we have to let it go at that.

When she came in she had this grapefruit sized mass in the right vault and tenderness in the left vault, and she might have had salpingitis. If she had gonorrheal salpingitis one would expect symptoms of dysuria, frequency and vaginal discharge when the disease was contracted. These are completely lacking, but in a female they might have been mild and overlooked. One would not expect gonococci on culture at the time of drainage. She might have had a hydrosalpinx which, four or five weeks after contracting the disease, would have been sterile on culture. Again, I should expect the sinus to heal unless there was a secondary infection or a tuberculous salpingitis. Although this thing had been going on for some months she was well-developed and nourished, not emaciated. With a tuberculous pelvic infection that goes on to secondary abscess formation, one would expect examination of the pelvis to show induration. It does not seem to be the picture of tuberculous salpingitis. However, this would explain the chronicity of the sinus tract.

Possibly she had a twisted ovarian cyst or even a pedunculated fibroid that was twisted. Either of these might have become gangrenous. In considering the possibility of perforation of the intestine, I should have mentioned that one would expect sudden prostration. In the same way, in a twisted pedunculated fibroid becoming gangrenous one would expect a sudden prostrating form of trouble. It was eight days, however, after symptoms started before she came to the hospital. Again, it says that the mass was a walled-off abscess, and it seems unlikely that the surgeon would not have seen that it was something queer or suggestive of gangrenous cyst or abscess from gangrene.

I think that the menstrual irregularity that she had does not necessarily mean that the primary trouble was in the ovaries or tubes. Any sort of inflammatory reaction in the lower abdomen or pelvis—and we know she had it—could easily involve the ovary and tube with adhesions, and so

forth, sufficient to give her irregularity. I do not believe that it is significant enough to point to the trouble as arising primarily in the pelvis.

How about syphilis? It might have been a broken-down gumma of the mesenteric nodes, but that is all I can say. There is no report of a Hinton test, and no history of contact. I think it is unlikely.

We must next consider unusual infections or infestations. This patient had been living in America, this rules out many of the tropical diseases. *Entameba histolytica* infection is unlikely, because that also comes in the category of perforation of the intestine. Actinomycosis might be the reason for keeping the sinus tract chronic. Actinomycosis of the intestines is not unknown without any other lesions. There is no history, however, of contamination from contact with straw and hay. We have to assume that granules might have been looked for in the smear which was said to be negative, but this does not necessarily rule out actinomycosis. The thing that does rule it out is that she was not emaciated and on the second entry had gained 13 lb. Furthermore, drainage of an actinomycotic abscess would not be adequate treatment, the disease would spread, with more sinus tracts and fistulas five weeks later. I believe she was not sick enough to have had it.

Then comes the question of the snails. Snails do serve as hosts for several parasitic organisms. Would it be fair to ask for a differential count?

DR TRACY B. MALLORY: On two smears the polymorphonuclears were 63 and 82 per cent respectively. No eosinophils were seen on either occasion. The lymphocytes were 16 and 12 per cent and the monocytes 4 and 16, respectively.

DR. STURGIS: I am sorry about that because I should like to have found a high eosinophilia. Apparently none were seen. In considering parasites in South Africa, the flukes or flat worms, schistosomes, are prevalent. I believe that there are no cases reported in America that cannot be traced to direct or indirect contact with the parts of the world where the parasite is prevalent. The schistosome parasite has an encysted state in snails, and human beings can be infected through the skin as well as by the oral route. The parasites may lodge in the pelvic veins where they develop to the adult stage. They have a tendency to locate in the rectum, ovary, bladder and sometimes in the appendix. It seems that a perfectly good case could be worked out for infestation with *Schistosomum hematobium*, the blood fluke, coming in snails in the encysted form, working through the skin, and lodging in the appendix, to give an appendiceal abscess. At the same time I suppose if that were the case she might have a generalized schistosomiasis in the pelvic veins and

give pain in the left side as well as the right, but there again, if a Meckel's diverticulum were inflamed and formed an abscess, one would expect to find *Bacillus coli* in the original drainage of the abscess and, again, that the sinus tract would heal or form a fecal fistula. It is possible that perforation of the intestine into the mesenteric border by foreign body, such as a porcupine quill or needle, might have caused a sterile abscess in the mesentery which could give such a picture as this, and if the foreign body did not come out in five weeks, I suppose it is possible that it might keep the tract open. But there is no history suggesting such possibility, and we have to let it go at that.

When she came in she had this grapefruit sized mass in the right vault and tenderness in the left vault, and she might have had salpingitis. If she had gonorrheal salpingitis one would expect symptoms of dysuria, frequency and vaginal discharge when the disease was contracted. These are completely lacking, but in a female they might have been mild and overlooked. One would not expect gonococci on culture at the time of drainage. She might have had a hydrosalpinx which, four or five weeks after contracting the disease, would have been sterile on culture. Again, I should expect the sinus to heal unless there was a secondary infection or a tuberculous salpingitis. Although this thing had been going on for some months she was well-developed and nourished, not emaciated. With a tuberculous pelvic infection that goes on to secondary abscess formation, one would expect examination of the pelvis to show induration. It does not seem to be the picture of tuberculous salpingitis. However, this would explain the chronicity of the sinus tract.

Possibly she had a twisted ovarian cyst or even a pedunculated fibroid that was twisted. Either of these might have become gangrenous. In considering the possibility of perforation of the intestine, I should have mentioned that one would expect sudden prostration. In the same way, in a twisted pedunculated fibroid becoming gangrenous one would expect a sudden prostrating form of trouble. It was eight days, however, after symptoms started before she came to the hospital. Again, it says that the mass was a walled-off abscess, and it seems unlikely that the surgeon would not have seen that it was something queer or suggestive of gangrenous cyst or abscess from gangrene.

I think that the menstrual irregularity that she had does not necessarily mean that the primary trouble was in the ovaries or tubes. Any sort of inflammatory reaction in the lower abdomen or pelvis—and we know she had it—could easily involve the ovary and tube with adhesions, and so

forth, sufficient to give her irregularity. I do not believe that it is significant enough to point to the trouble as arising primarily in the pelvis.

How about syphilis? It might have been a broken-down gumma of the mesenteric nodes, but that is all I can say. There is no report of a Hinton test, and no history of contact. I think it is unlikely.

We must next consider unusual infections or infestations. This patient had been living in America, this rules out many of the tropical diseases. *Entameba histolytica* infection is unlikely, because that also comes in the category of perforation of the intestine. Actinomycosis might be the reason for keeping the sinus tract chronic. Actinomycosis of the intestines is not unknown without any other lesions. There is no history, however, of contamination from contact with straw and hay. We have to assume that granules might have been looked for in the smear which was said to be negative, but this does not necessarily rule out actinomycosis. The thing that does rule it out is that she was not emaciated and on the second entry had gained 13 lb. Furthermore, drainage of an actinomycotic abscess would not be adequate treatment, the disease would spread, with more sinus tracts and fistulas five weeks later. I believe she was not sick enough to have had it.

Then comes the question of the snails. Snails do serve as hosts for several parasitic organisms. Would it be fair to ask for a differential count?

DR TRACY B. MALLORY. On two smears the polymorphonuclears were 63 and 82 per cent respectively. No eosinophils were seen on either occasion. The lymphocytes were 16 and 12 per cent and the monocytes 4 and 16, respectively.

DR. STURGIS. I am sorry about that because I should like to have found a high eosinophilia. Apparently none were seen. In considering parasites in South Africa, the flukes or flat worms, schistosomes, are prevalent. I believe that there are no cases reported in America that cannot be traced to direct or indirect contact with the parts of the world where the parasite is prevalent. The schistosome parasite has an encysted state in snails, and human beings can be infected through the skin as well as by the oral route. The parasites may lodge in the pelvic veins where they develop to the adult stage. They have a tendency to locate in the rectum, ovary, bladder and sometimes in the appendix. It seems that a perfectly good case could be worked out for infestation with *Schistosomum hematobium*, the blood fluke, coming in snails in the encysted form, working through the skin, and lodging in the appendix, to give an appendiceal abscess. At the same time I suppose if that were the case she might have a generalized schistosomiasis in the pelvic veins and

the time of the first operation no effort was made to find the appendix. At the second operation we explored the peritoneal cavity, still laboring under the mistaken idea that we had drained an appendiceal abscess. When she came in the second time as Dr Sturgis logically pointed out, the sinus should have discharged fecal material or it should have closed had the original trouble been caused by her appendix. I made a paramedian incision and under the McBurney incision found the sinus tract matted with coils of intestine. These I freed and found that the sinus tract continued down to a point over the great vessels in the pelvis. There the sinus tract apparently entered into a lymph node in that region. There was a mass involving the right tube and ovary. The left tube was not strikingly abnormal save for small nodules along it. Similar nodules were more easily seen on the right side, where the mass was present. The uterus was tied down, chiefly posteriorly, by adhesions that could be separated fairly readily and seemed of long standing rather than of short duration. When I saw the appearance of the pelvis the impression I gathered was that it was probably pelvic inflammatory disease. We asked one of the pathologists to come over, and I excised one of the small nodules that appeared on the tube and gave it to him to section. It was about 0.75 cm in diameter, and on section it was seen to have a well-formed wall with a caseous center. He was completely satisfied that it represented tuberculosis. At the end of the first operation the diagnosis was acute appendiceal abscess. At the second operation the diagnosis was tuberculous salpingitis, after about a week of making myself a nuisance to Dr Mallory we got as far as schistosoma salpingitis, and after a much longer period than Dr Sturgis took, we arrived at the correct diagnosis.

DR. MALLORY: This gross appearance of the tubes is apparently very characteristic of the condition which has been reported several times in the American and German literature as pseudo-tuberculosis, apparently due to pinworms.

DR. JOE V. MEIGS: You find pinworms in appendices. Do they ever perforate?

DR. MALLORY: A significant percentage perhaps 1 or 2 per cent, of appendices contain pinworms, perhaps more than that in children. In all the literature on the subject there are only one or two papers suggesting that they penetrate its wall, and those are under a cloud of doubt. On the other hand this invasion of the peritoneal cavity via the female genital tract is perfectly well established.

DR. Faxon: I might say that the appendix was retrocecal and now here near the mass in the pelvis.

It was perfectly free and grossly normal, on section no lesion was found.

DR. FRANCIS T. HUNTER: In the literature is eosinophilia mentioned?

DR. MALLORY: It usually is found in the local reaction around the ova, but not mentioned in the blood.

A PHYSICIAN: Did you find the worms?

DR. MALLORY: We made the correct diagnosis long after the patient had gone home. She was not examined for pinworms.

A PHYSICIAN: Were any whole worms found in the specimen?

DR. MALLORY: No, just the ova, the worms had been destroyed by inflammatory reaction whereas the ova were more resistant and remained behind to produce a foreign-body reaction that closely resembled tuberculosis.

CASE 24072

PRESENTATION OF CASE

A forty-eight-year-old, white, American housewife entered the hospital with the complaint of severe abdominal pain of thirty-six hours' duration.

She was well and healthy until about six weeks before entry, when she had "intestinal gripe" of three or four days' duration. Epigastric pain was the only symptom she remembered at that time. Thirty-six hours before entry, she was suddenly awakened in the morning by a sharp, gripping, midepigastric pain which made her cry out. She got out of bed, defecated a small amount, and vomited some normal-appearing gastric contents. Her physician was called and gave her a hypodermic injection which eased but did not abolish the pain. During the course of the day and evening the pain shifted to the lower abdomen and became cramplike in character. She was given another hypodermic and took "small white pills" every hour. The following morning the pain was somewhat less severe and still localized in the lower part of the abdomen. She had no further vomiting but felt quite nauseated, had anorexia, and raised considerable amounts of gas. Since the defecation at the time of the onset of the pain, she had passed neither gas nor feces by rectum. About eight hours before entry she was given an enema with little result. She had had no cardiorespiratory or genitourinary symptoms, and her menstrual history was negative. Her past history and family history were noncontributory.

Physical examination revealed a well-developed but somewhat emaciated woman sitting upright in bed, breathing rapidly, in obvious discomfort. The skin was dry and flushed, and the tongue

pelvic peritoneum, which would explain the things that puzzled me before—the large abscess medial to the cecum and her generalized abdominal tenderness and spasm. The discharge of eggs through the sinus would also explain its chronicity. Perhaps the snail was put in to make it harder, but I will stand by my diagnosis.

PREOPERATIVE DIAGNOSIS

Residual appendiceal abscess

DR STURGIS'S DIAGNOSES

Schistosoma infection of appendix with abscess formation

Generalized schistosomiasis of pelvic peritoneum

ANATOMICAL DIAGNOSIS

Oxyuris infection of the salpinx and pelvic peritoneum

PATHOLOGICAL DISCUSSION

DR MALLORY: We have been made very conscious of schistosoma by the recent visit of two South Africans here, and that question came up very definitely in this case after we had examined the tube and found in its walls a lot of peculiar looking ova. However, when we sent the material to some of the experts in the Department of Comparative Pathology at the Harvard Medical School they failed to confirm our suspicions. The accompanying photomicrograph shows a typical

microscopic field. In the upper left-hand corner is a huge giant cell. Below its right-hand end are four or five lozenge-shaped masses with dark central areas and clear hyaline capsules around them. Five or six of these ova are twice as big as the others. True schistosoma have spines, which

are easily made out. Whether they are at the end or on the side distinguishes the different species. When the ova in this case were compared with schistosoma it was evident that they were too small, and, moreover, we were unable to find any spines, which are so characteristic of schistosoma. However, sometimes in a section it is difficult to make out the spine because the ova may have been cut at the wrong angle. The ova which most closely correspond in appearance to these are those of the ordinary pinworm, *Oxyuris vermicularis*. With a little research on the part of the laboratory staff we have found a number of papers* reporting about 20 cases of pinworm infestation of the tubes or the peritoneal cavity. Peritoneal infestation has never been reported in males. In many of these cases it has been possible to find the pinworms in the vagina, uterus or tubes, evidently on the way up the genital tract. So I think there is no question that in this case the worms must have climbed up through the vagina and uterus. Whether the inflammatory reaction that develops in these cases is due entirely to the pinworm or whether there is a secondary bacterial inflammation has never been determined with certainty. In most of the reported cases no cultures have been taken. We have in this case the original culture of the abscess, which was sterile, so that we have some evidence against a synchronous bacterial infection.

The gross appearances at operation were very interesting, I am going to ask Dr Faxon to tell about them.

DR HENRY H FAXON: We did not give the same imaginative thought to the problem that Dr Sturgis has, and with a tender right-lower-quadrant mass we were satisfied that it was an appendix abscess and it was drained. I should like to congratulate him on sorting out the salient features of the history—the mention of snails from South Africa, the bacteriology and the persistent sinus. We were surprised that with an abscess of appendiceal origin there was not more odor to the pus, and with a little more imagination we should have more properly evaluated the findings, but even at the time of discharge we felt that we had been dealing with an appendiceal abscess.

The reason for re-entry was to have an appendectomy performed in accord with our policy that if drainage of an appendiceal abscess has been performed without removal of the appendix, then appendectomy should be carried out two or three months after the first operation to prevent the more than likely chance of future attacks. the time of the first operation no effort was made to find the appendix. At the second operation we explored the peritoneal cavity, still laboring under the mistaken idea that we had drained an appendiceal abscess. When she came in the second time as Dr Sturgis logically pointed out, the sinus should have discharged fecal material or it should have closed had the original trouble been caused by her appendix. I made a paramedian incision and under the McBurney incision found the sinus tract matted with coils of intestine. These I freed and found that the sinus tract continued down to a point over the great vessels in the pelvis. There the sinus tract apparently entered into a lymph node in that region. There was a mass involving the right tube and ovary. The left tube was not strikingly abnormal save for small nodules along it. Similar nodules were more easily seen on the right side, where the mass was present. The uterus was tied down, chiefly posteriorly, by adhesions that could be separated fairly readily and seemed of long-standing rather than of short duration. When I saw the appearance of the pelvis the impression I gathered was that it was probably pelvic inflammatory disease. We asked one of the pathologists to come over, and I excised one of the small nodules that appeared on the tube and gave it to him to section. It was about 0.75 cm in diameter, and on section it was seen to have a well-formed wall with a caseous center. He was completely satisfied that it represented tuberculosis. At the end of the first operation the diagnosis was acute appendiceal abscess; at the second operation the diagnosis was tuberculous salpingitis, after about a week of making myself a nuisance to Dr Mallory we got as far as schistosoma salpingitis, and after a much longer period than Dr Sturgis took, we arrived at the correct diagnosis.

DR MALLORY This gross appearance of the tubes is apparently very characteristic of the condition which has been reported several times in the American and German literature as pseudo-tuberculosis, apparently due to pinworms.

DR JOE V MEIGS You find pinworms in appendices. Do they ever perforate?

DR MALLORY A significant percentage, perhaps 1 or 2 per cent, of appendices contain pinworms, perhaps more than that in children. In all the literature on the subject there are only one or two papers suggesting that they penetrate its wall, and those are under a cloud of doubt. On the other hand this invasion of the peritoneal cavity via the female genital tract is perfectly well established.

DR FAYON I might say that the appendix was retrocecal and nowhere near the mass in the pelvis.

It was perfectly free and grossly normal, on section no lesion was found.

DR FRANCIS T HUNTER In the literature is eosinophilia mentioned?

DR MALLORY It usually is found in the local reaction around the ova, but not mentioned in the blood.

A PHYSICIAN Did you find the worms?

DR MALLORY We made the correct diagnosis long after the patient had gone home. She was not examined for pinworms.

A PHYSICIAN Were any whole worms found in the specimen?

DR MALLORY No, just the ova, the worms had been destroyed by inflammatory reaction whereas the ova were more resistant and remained behind to produce a foreign-body reaction that closely resembled tuberculosis.

CASE 24072

PRESENTATION OF CASE

A forty-eight-year-old, white, American housewife entered the hospital with the complaint of severe abdominal pain of thirty-six hours' duration.

She was well and healthy until about six weeks before entry, when she had "intestinal grippe" of three or four days' duration. Epigastric pain was the only symptom she remembered at that time. Thirty-six hours before entry, she was suddenly awakened in the morning by a sharp, gripping, midepigastria pain which made her cry out. She got out of bed, defecated a small amount, and vomited some normal-appearing gastric contents. Her physician was called and gave her a hypodermic injection which eased but did not abolish the pain. During the course of the day and evening the pain shifted to the lower abdomen and became cramplike in character. She was given another hypodermic and took "small white pills" every hour. The following morning the pain was somewhat less severe and still localized in the lower part of the abdomen. She had no further vomiting but felt quite nauseated, had anorexia, and raised considerable amounts of gas. Since the defecation at the time of the onset of the pain, she had passed neither gas nor feces by rectum. About eight hours before entry she was given an enema with little result. She had had no cardiorespiratory or genitourinary symptoms, and her menstrual history was negative. Her past history and family history were noncontributory.

Physical examination revealed a well-developed but somewhat emaciated woman sitting upright in bed, breathing rapidly, in obvious discomfort. The skin was dry and flushed, and the tongue

was rough and coated. The heart and lungs were negative, and the blood pressure was 126 systolic, 72 diastolic. The abdomen showed boardlike spasm and was moderately distended. There was diffuse tenderness, most marked in the left lower quadrant, and peristalsis was absent. Liver dullness appeared to be normal, and no fluid or masses could be made out. She was unable to lie flat in bed because of the abdominal spasm. Pelvic examination showed diffuse tenderness in both vaults. The fundus of the uterus could not be made out. There was exquisite tenderness on moving the cervix. Rectal examination showed tenderness with questionable bulging of the walls.

The temperature was 101.5°F, the pulse 120. The respirations were 20.

The urine examination was negative except for a very slight trace of albumin. The blood showed a red-cell count of 3,750,000 and a white-cell count of 29,700.

An x-ray of the abdomen showed the diaphragm high on both sides, although somewhat indistinct in outline because of hazy dullness in the lower lung fields. The costophrenic angles were shallow, and the upper lung fields were clear. The heart shadow was not remarkable. There was no evidence of free gas beneath the diaphragm.

During the two days following entry her temperature rose gradually to 104°F, and her pulse to 135. On the third day the nonprotein nitrogen of the blood was 22 mg per cent, and the chlorides were equivalent to 99 cc of N/10 sodium chloride. The white-cell count of the blood was 3300. She died on the fourth day.

DIFFERENTIAL DIAGNOSIS

DR. JOHN D. STEWART: When this patient was first seen she was not in shock, although she may have been after the onset of her abdominal pain, thirty-six hours previously. We see patients who, following the onset of an abdominal catastrophe, go into a state of shock which is compensated for during the subsequent day or two, only to recur perhaps as a terminal phenomenon. At the time of entry it is a perfectly good picture of peritonitis, there being nothing lacking to make the diagnosis.

DR. GEORGE W. HOLMES: This film was taken in the upright position and ought to show gas if present. The whole picture is that of a process below rather than above the diaphragm. The diaphragm is high, and its outline hazy. This might be extension of the inflammatory process to involve the diaphragm. I see no process in the chest to account for the haziness.

DR. STEWART: Could it be taken as evidence of basal atelectasis?

DR. HOLMES: It might, but I doubt it.

DR. STEWART: This is to me a very interesting picture. It involves the differential diagnosis of the acute abdomen. Time is short, so I will not attempt to go into the differential as fully as I otherwise might. It seems to me that the outstanding feature in the case on which we might base a diagnosis is sudden violent pain in a previously healthy person—a pain so severe that two doses of morphine and possibly sedatives by mouth were required to relieve it. Another important point is the rapid development of peritonitis, because I think it is fair to conclude that she died of general peritonitis. Another point of considerable interest to me is the fact that the gastrointestinal symptoms were minimal. She had reflex vomiting only immediately after the onset of the pain. She had no diarrhea, and passed no bloody material by rectum. Another very important point is the question of localization of tenderness. When you are confronted with such a picture as this, perhaps the most important point in making the diagnosis is localization of maximal tenderness, and that is often possible even in the presence of boardlike spasm and general tenderness. We are told that her maximum tenderness was in the lower abdomen, chiefly on the left, and a good deal is made of pelvic tenderness on pelvic examination. Those findings are probably very significant. Another interesting point is the shift in pain, which began in the epigastrium and subsequently was most marked in the lower abdomen. There are two questions that particularly come to one's mind in this case. One is why this patient was not operated on. It is possible that this was due to confusion in diagnosis and that when it became apparent that she had peritonitis it was considered better to treat her supportively. Another point of interest is the anemia, which apparently was real,—a red-cell count of 3,750,000,—if it is fair to assume it was not due to technical error.

In going over the differential diagnosis we can immediately exclude the extra-abdominal lesions which simulate acute abdomen. I do not believe this is coronary disease or diaphragmatic pleurisy or any of the other lesions above the diaphragm that produce abdominal symptoms. Likewise, I think we can exclude the urinary tract as the source of the symptoms. Then we are brought to the consideration of the classical trio of lesions which produce sudden severe abdominal pain in a previously healthy person, namely acute pancreatitis, perforation of a peptic ulcer and acute small bowel intestinal obstruction. With perforation of peptic ulcer it is not necessary to have a history of dyspepsia preceding perforation. Twenty-five to 50 per cent of the cases in various series of cases

do not give such a history. In regard to the matter of gas beneath the diaphragm—free gas in the peritoneal cavity—the fact that the x-ray does not show any does not exclude the possibility of perforated ulcer. In about 50 per cent of the cases of perforated ulcer we do not succeed in demonstrating this sign. However, I think a perforated ulcer would not be my first diagnosis, particularly because the patient apparently had lower abdominal tenderness dominating the picture at the time of examination and because the pain was chiefly lower abdominal during her course in the hospital. To be sure, exudate can flow down into the pelvis and produce peritonitis in that region as well as in the rest of the abdomen, but in perforated peptic ulcer the predominating tenderness ought to be near the site of perforation and the spasm there should be more marked. Acute hemorrhagic pancreatitis produces violent pain and immediate shock and the course is often brief, as it was in this case. One of the striking features of acute hemorrhagic pancreatitis is persistent nausea and vomiting. We should also have some story of pain in the back, and tenderness should have been most marked over the region of the pancreas rather than in the left lower quadrant. Without going into that further, I shall pass that by as not being the most likely diagnosis, although it is a good possibility.

Acute obstruction of the upper intestine could produce as violent a picture as this with very severe pain. Torsion of the small bowel may lead to immediate prostration with subsequent peritonitis, if not corrected by operation. This patient vomited only once, according to the story, and the pain presently became lower abdominal rather than upper abdominal. Nevertheless, I believe that strangulation of a part of the intestine without complete occlusion is a possibility. Internal concealed hernia, or Richter's hernia, can give this picture and go on to peritonitis, but I feel that that probably is not the most likely diagnosis. Primary pelvic lesions I shall also pass over as being unlikely. To be sure twisted ovarian cyst can produce sudden abdominal pain and may lead to peritonitis, but I believe that the development of peritonitis would take longer than apparently was required in this case, and furthermore there is no note of any palpable mass in the pelvis on pelvic examination. Other pelvic lesions such as ruptured ectopic pregnancy seem very unlikely. So we are reduced to a consideration of some perforative lesion of the gastrointestinal tract, or possibly of the gall bladder, with a rapid development of peritonitis. The question of acute cholecystitis or plugging of the cystic duct with stone and sub-

sequent rupture of the gall bladder would have to be considered. The attack of pain which she had had six weeks previously might have been on the basis of a cholecystitis. However it seems fair to expect that the examiner in the case would have detected greater tenderness in the abdomen in the region of the gall bladder and persistence of pain in the upper abdomen. Then there is the question of acute appendicitis with obstruction and possibly with fecalith in the lumen of the appendix. This would be a very unusual picture of acute appendicitis, but acute appendicitis is notable for its varied manifestations. We have seen patients operated on for perforated ulcer who have had obstructive appendicitis with perforation subsequent to the obstruction. In view of the predominance of tenderness and pain in the lower abdomen and particularly in view of the story of shift in pain from upper to lower abdomen I think that that is not an unreasonable diagnosis. There are unusual lesions which might produce the same picture, for example, perforation of an ulcer of a Meckel's diverticulum. Except for the fact that it is very rare, there is nothing wrong with making that diagnosis here.

I am unable to tie up the diagnosis with the anemia that the patient had unless she had had an ulcer in the gastrointestinal tract which had been bleeding and which subsequently ruptured. So I should say that this patient had diffuse peritonitis most likely following perforation of some part of the gastrointestinal tract, and that the appendix or a Meckel's diverticulum is as reasonable a source as any.

DR GEORGE W. W. BREWSTER: How about mesenteric thrombosis?

DR TRACY B. MALLORY: Do you raise that as a possibility, or is that your diagnosis?

DR BREWSTER: I think it is possible.

DR STEWART: I had considered that in my own mind and discarded it because of the lack of gastrointestinal symptoms. Also, I doubt if a patient would live four or five days with as fulminating a process as that usually is.

DR MALLORY: Of all the acute abdominal emergencies I think mesenteric thrombosis is the hardest to diagnose and the least often successfully diagnosed. That is what this patient had.

CLINICAL DIAGNOSES

Peritonitis, cause undetermined
Bronchopneumonia

DR STEWART'S DIAGNOSES

General peritonitis from perforation of gastrointestinal tract

Acute obstructive appendicitis?
Perforation of Meckel's diverticulum? '

ANATOMICAL DIAGNOSES

Mesenteric thrombosis, arterial and venous
Gangrene of ileum
Embolus to the superior mesenteric artery
Thrombosis of right adrenal vein with hemorrhage into adrenal
Arteriosclerosis moderate, aortic, with mural thrombosis
Peritonitis, acute focal
Nephritis, chronic vascular
Cortical adenoma of right adrenal
Pulmonary congestion and edema
Pleuritis, chronic fibrous, bilateral
Leiomyomas of uterus

PATHOLOGICAL DISCUSSION

DR MALLORY The terminal ileum for the last three feet was acutely inflamed and gangrenous. The superior mesenteric artery was occluded by clots evidently originating in an embolus, and the source of the embolus was a mural thrombus in the aorta immediately above and partly around the mouth of the superior mesenteric artery itself. There was a secondary thrombosis of the superior mesenteric vein which looked fresher than the arterial one. It extended the whole length of the vein and a short way up the portal vein, and had begun to extend into the splenic vein. That, however, was very recent. There were no changes in the liver or spleen. We found nothing to account for the anemia. The diagnosis on the ward was general peritonitis, cause undetermined. They refused to guess.

WHAT PRICE STANDARDS?

THAT there is a group of persons vigorously opposed to raising the standards of qualification for practicing the healing art in Massachusetts is shown by the number and character of the bills introduced for consideration by the General Court this year.

It was in May, 1936, that the governor signed the bill creating an Approving Authority for colleges giving premedical education and for medical schools, and the effective date for the beginning of this authority was, then set by the statute as January 1, 1939. As that date draws near, renewed and intensive efforts are being made to bring to nought this legislation, which was designed to protect the people of the Commonwealth against improperly qualified practitioners of the healing art. Nine bills have been introduced, the result, if not

the intent, of which would be to expose the sick either to the risk of having continued the intolerably low standards of qualification for practice under which Massachusetts has suffered for decades and which other states have left far behind or in some branches of the healing art, to the risk of having treatment by less qualified persons than are at present permitted to practice.

The first, House Bill 758, proposes to postpone the effective date of the beginning of the activity of the Approving Authority for three years, that is, from 1939 to 1942. The present provision gives over six years to schools in which to make the changes that are necessary in order to receive approval. The bill became a law in 1936, and the provisions do not apply to candidates matriculating before January 1, 1939. Since most medical students matriculate in September, the class entering in the fall of 1939 will be the first one affected. At that time only the first year of the school will have to be approved, in September, 1940, only the first and second years, in September, 1941, only the first, second and third years, and the whole four year course not until September, 1942. If any school is seriously preparing to meet the generally accepted standards and is at all likely to meet them, six years and four months would seem to be a generous allowance of time. If the schools are asking for nearly ten years, it is a fair question to ask whether they will use the time to try to change themselves or to change the statute. That someone, perhaps some school, seeks to change the statute, making it of no effect so far as it concerns institutions in Massachusetts, is shown by House Bills 1084, 1133, 1195 and 1341.

There are now four non-approved medical schools in the United States, of which two are in Massachusetts. Why should these be given special privileges? Why should the people of Massachusetts be especially exposed to the danger of poorly qualified practitioners? Under ordinary circumstances no other state will admit recent graduates of these two Massachusetts schools to practice within its borders.

There are two bills (Senate 282 and House 759) seeking to create a separate board of registra-

Acute obstructive appendicitis?
Perforation of Meckel's diverticulum? '

ANATOMICAL DIAGNOSES

Mesenteric thrombosis, arterial and venous
Gangrene of ileum
Embolus to the superior mesenteric artery
Thrombosis of right adrenal vein with hemorrhage into adrenal
Arteriosclerosis moderate, aortic, with mural thrombosis
Peritonitis, acute focal
Nephritis, chronic vascular
Cortical adenoma of right adrenal.
Pulmonary congestion and edema
Pleuritis, chronic fibrous, bilateral
Leiomyomas of uterus

PATHOLOGICAL DISCUSSION

DR MALLORY The terminal ileum for the last three feet was acutely inflamed and gangrenous. The superior mesenteric artery was occluded by clots evidently originating in an embolus, and the source of the embolus was a mural thrombus in the aorta immediately above and partly around the mouth of the superior mesenteric artery itself. There was a secondary thrombosis of the superior mesenteric vein which looked fresher than the arterial one. It extended the whole length of the vein and a short way up the portal vein, and had begun to extend into the splenic vein. That, however, was very recent. There were no changes in the liver or spleen. We found nothing to account for the anemia. The diagnosis on the ward was general peritonitis, cause undetermined. They refused to guess.

Senate 282—An act establishing a board of examination and registration in osteopathy. Public Health, February 17

House 758—An act relative to the qualifications of applicants for registration as qualified physicians. Public Health, March 1

House 759—An act creating a board of examination and registration in osteopathy. Public Health, March 1

House 85—An act relative to the practice of chiropractic. Public Health, March 5

House 1054—An act to preserve the rights of graduates of educational institutions chartered by the Commonwealth of Massachusetts. State Administration, February 23

House 1153—An act providing for special examinations for graduates of certain Massachusetts educational institutions. Education, March 5

House 1195—An act requiring boards of registration and examination to examine certain applicants. Public Health, March 1

House 1210—An act creating a board of examination and registration to regulate the practice of magnetic healers. State Administration, February 15

House 1341—"An act to further regulate the conduct of examinations by boards of registration of graduates of institutions of learning. This bill has not been printed and the exact wording of the title has not been stated. Education, March 5

PETTIFOGGING PETTY POLITICS

It is axiomatic that politics have no place in anything that concerns the health of the public. This is recognized by everybody except the less desirable type of politician.

Being necessarily intimately concerned with the health of the public in its more sensational aspects, the Boston City Hospital has always been the target for attacks by politicians. They have also tried to use its various departments as sources of reward for their creditor constituents. Such an attempt was made—early in its history—to control staff appointments. This, of necessity, failed and the staff has been completely free from such domination for a long time. Then the buying of supplies was tampered with. This too was corrected by impetus provided through the staff, a department of which exposed and forcibly stopped the sale of grossly infected low-grade milk. After the War it was notorious that the hiring and discharging of the lesser-paid employees rested in political hands, and the long, hard battle necessary to correct this evil has only recently been won. Finally, the custom of using hospital beds, private rooms and the services of the medical and surgical staffs

not only without any monetary compensation but even without the small courtesy of a "thank you" has also been stopped. This vicious racket involved politicians, their families, friends, neighbors and constituents and led directly to overcrowding the use of the hospital facilities by those not entitled to them, the giving of false addresses by patients and a resulting lack of efficiency in the care that the legitimate patients required. With a strict enforcement of the rule requiring payment of hospital bills every two weeks in advance and a thorough skilled investigation before admitting all non-emergency cases, this source of petty plunder, like the staff, the purchase of supplies and the control of non-civil-service employees, has been rudely taken away.

Only the nursing school remains as a means of granting favors. It is to be presumed that the nurses have been immune from this sort of thing in the past because, in the first place, they were ladies and it is hard to bring oneself to include ladies in schemes of this sort, and in the second place, all politicians up to the present had too much self-respect to stoop to such measures for the mending of their political fences. However, times are hard, a new city administration is starting, and economies, including salary cuts, are in the air. Reports have it that grave evil has been done to the taxpayers by the reorganization of the nursing school at the Boston City Hospital. It is difficult to understand how a reorganization that aims only to increase nurses' education and nursing efficiency, and that has been effected after prolonged and meticulous investigation by men experienced in all phases of hospital administration, can do the taxpayers anything but good.

It is time to put a permanent stop to such insensate baiting. The question today is not whether the nursing school at the Boston City Hospital is run well or badly. That can be safely left to the Trustees and staff. The question rather is: Shall patients be subjected to less and poorer care than they have every right to expect because the administration of the hospital is to be hamstrung every time some minor holder of political office takes it into his head to get some publicity?

tion for osteopathic physicians. Why do osteopaths seek this separation? They now fulfill the same qualifications for examination as do graduates of regular medical schools, they take the same examinations, and if registered, they practice under the same conditions—they may operate, give drugs, practice obstetrics, sign death certificates. They are eligible to sit on the Board of Registration in Medicine on exactly the same conditions as other physicians. What more can they possibly want? They ask for exactly the same rights and privileges, after registration, as other physicians possess, and they ask that all this be procured in an easier way. They want their own board to be the approving authority for their schools, in accordance with requirements which are notably and notoriously substandard. These bills represent an endeavor to escape from the jurisdiction of the Approving Authority, the creation of which the osteopathic profession opposed so vigorously in 1936. One of the bills (Senate 282) provides for registration without education,—high school, college or medical school,—without degree, and without examination.

Then there are the bills (House 854 and 1210) for the chiropractors and the magnetic healers. Both osteopathy and chiropractic, as such, are on the wane. They represent theories of the purely mechanical origin of all disease and are not to be classed with medical specialties which consider only a limited portion of the body and its functions. They treat any and all manifestations of disease in any part of the body as due to a single cause—the “osteopathic lesion,” or a subluxation of the spine as determined by “chiropractic analysis.” Materialism in its broadest sense is inadequate enough in explaining diseases of human beings, but when materialism is limited to mechanics, no one can take the theory too seriously. The magnetic healers are in a different class—they do not even claim an objective test of the power of magnetic healing. “I know I have the power of healing” seems to be the only test. As it would obviously be impossible for any individual or group of individuals to determine the presence of such a “gift” in another, it is difficult to comprehend how any board would be able to act in such a way

as to eliminate those self-designated healers who are disillusioned.

What should be, what shall be, the attitude of the medical profession toward these practitioners of the healing art? There can be only one reasonable position—all persons who desire to treat the sick in Massachusetts should meet certain minimum standards of qualification as to age, moral character, education, and proficiency as tested by examination. These standards should be the same for all. When the standards of qualification are once met and the practitioner once registered, he should be free to employ such methods of treatment as his intelligence, his training and his conscience indicate.

What should be, what shall be, the attitude of the public toward lowering of standards of practice for the healing art? It should be opposed, and will be opposed if the medical profession, to which it still looks for enlightenment on medical matters, can inform it intelligently and persuasively wherein the danger lies and in what the danger consists. The members of the medical profession should meet this responsibility squarely and carry it manfully, instead of shrugging their shoulders and saying pityingly, “If the public wants and prefers quacks and ignorant fellows to treat its ailments, let it have what it wants.” The physician has a social responsibility, which he must not shirk. All these bills are opposed by the Committee on State and National Legislation of the Massachusetts Medical Society. It is the duty of the district medical societies to send representatives to the legislative hearings in order to voice such opposition, and they should not fail.

The price of standards, ever higher standards, for the care of the sick and suffering is eternal vigilance and eternal warfare—unceasing warfare against prejudice and selfishness and greed and ignorance, against the debasing of standards for any cause—“ceaseless devotion to the cause of humanity.”

* * *

The bills, with abbreviated titles, the legislative committees to which they have been referred, and the dates of the hearings, are as follows

Senate 282—An act establishing a board of examination and registration in osteopathy. Public Health, February 17

House 758—An act relative to the qualifications of applicants for registration as qualified physicians. Public Health, March 1

House 759—An act creating a board of examination and registration in osteopathy. Public Health, March 1

House 837—An act relative to the practice of chiropractic. Public Health, March 5

House 1084—An act to preserve the rights of graduates of educational institutions chartered by the Commonwealth of Massachusetts. State Administration, February 23

House 1155—An act providing for special examinations for graduates of certain Massachusetts educational institutions. Education, March 5

House 1195—An act requiring boards of registration and examination to examine certain applicants. Public Health, March 1

House 1210—An act creating a board of examination and registration to regulate the practice of magnetic healers. State Administration, February 18

House 1341—An act to further regulate the conduct of examinations by boards of registration of graduates of institutions of learning. This bill has not been printed and the exact wording of the title has not been stated. Education, March 8

PETTIFOGGING PETTY POLITICS

It is axiomatic that politics have no place in anything that concerns the health of the public. This is recognized by everybody except the less desirable type of politician.

Being necessarily intimately concerned with the health of the public in its more sensational aspects, the Boston City Hospital has always been the target for attacks by politicians. They have also tried to use its various departments as sources of reward for their creditor constituents. Such an attempt was made—early in its history—to control staff appointments. This, of necessity, failed and the staff has been completely free from such domination for a long time. Then the buying of supplies was tampered with. This too was corrected by impetus provided through the staff, a department of which exposed and forcibly stopped the sale of grossly infected low-grade milk. After the War it was notorious that the hiring and discharging of the lesser-paid employees rested in political hands, and the long, hard battle necessary to correct this evil has only recently been won. Finally, the custom of using hospital beds, private rooms and the services of the medical and surgical staffs

not only without any monetary compensation but even without the small courtesy of a "thank you" has also been stopped. This vicious racket involved politicians, their families, friends, neighbors and constituents and led directly to overcrowding, the use of the hospital facilities by those not entitled to them, the giving of false addresses by patients, and a resulting lack of efficiency in the care that the legitimate patients required. With a strict enforcement of the rule requiring payment of hospital bills every two weeks in advance and a thorough skilled investigation before admitting all non-emergency cases, this source of petty plunder, like the staff, the purchase of supplies and the control of non-civil-service employees, has been rudely taken away.

Only the nursing school remains as a means of granting favors. It is to be presumed that the nurses have been immune from this sort of thing in the past because, in the first place, they were ladies and it is hard to bring oneself to include ladies in schemes of this sort, and in the second place, all politicians up to the present had too much self-respect to stoop to such measures for the mending of their political fences. However, times are hard, a new city administration is starting, and economies, including salary cuts, are in the air. Reports have it that grave evil has been done to the taxpayers by the reorganization of the nursing school at the Boston City Hospital. It is difficult to understand how a reorganization that aims only to increase nurses' education and nursing efficiency, and that has been effected after prolonged and meticulous investigation by men experienced in all phases of hospital administration, can do the taxpayers anything but good.

It is time to put a permanent stop to such insensate bawling. The question today is not whether the nursing school at the Boston City Hospital is run well or badly. That can be safely left to the Trustees and staff. The question rather is: Shall patients be subjected to less and poorer care than they have every right to expect because the administration of the hospital is to be hamstrung every time some minor holder of political office takes it into his head to get some publicity?

The answer can only be, No. The sooner and the more unequivocally the Trustees make that answer the more efficient will be the hospital, and the better the care and health of the Boston public—politicians included

NATIONAL DEFENSE WEEK

MILITARY medicine and civil medicine are so different that the practitioner flounders when the former is thrust upon him. Diagnosis and treatment en masse is entirely different from that in the office and home and cannot be learned in a few days—to say nothing of the paper work that is so exasperatingly puzzling.

All such things are brought to mind by National Defense Week, which, as usual, is being celebrated between February 12 and 22. It is sponsored by the Reserve Officers' Association to acquaint the public with the status and needs of national defense, and serves to drive home the point that the medical reserve officer in times of peace should take advantage of the courses that are made available to him for instruction in military medicine.

CORRECTION

In the paper by Wiggin and Tartakoff, entitled "The Use of Combined Pontocaine and Novocain for Spinal Anesthesia," which appeared in the January 27 issue of the *Journal*, the fifth line from the bottom in the second column on page 171, which reads, in part, "at a rate of 0.5 cc per minute," should be changed to read "at a rate of 0.5 cc. per second."

SECTION OF OBSTETRICS AND GYNECOLOGY

M. FLETCHER EADES, M.D., *Secretary*
19 Bay State Road
Boston

CASE HISTORY No. 59 PLACENTA ABLATIO AT TERM

Mrs. W. B., a white woman, aged thirty-seven, in her twelfth pregnancy, was seen in the clinic on January 1, 1937, when two months pregnant.

A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

Her family history was essentially negative. Her past history was negative except for scarlet fever at fifteen years of age. Ten pregnancies and labors had been normal, and it was known that in the eleventh pregnancy the blood pressure had been normal and the urine had shown no albumin. Her periods had always been regular with a twenty-eight-day cycle, lasting five days without pain. Her last menses started on October 26, 1936, making the estimated date early in August, 1937.

Physical examination showed a well-developed and nourished woman. Her heart showed no enlargement, there were no murmurs. The hemoglobin was 90 per cent (Sahli), and the blood pressure was 116 systolic, 72 diastolic. The lungs showed no rales or dullness. The extremities were normal. Vaginal examination showed the uterus to be enlarged, consistent with her dates. Her urine showed a specific gravity of 1.008, there was no albumin or sugar, and no pus, blood or casts.

She was seen each month in the clinic until two weeks before the baby was due. At this time her blood pressure was found to be 176 systolic, 96 diastolic. There was no albumin in the urine. She was told to take plenty of rest, to restrict the intake of salt, to take a daily dose of Epsom salts and to return in one week. However, she did not return to the clinic.

On July 27, she entered the hospital at 1:45 a.m. with cramp-like abdominal pains occurring every three minutes, which had been present for one hour. Her temperature was 98.4°F, and her pulse 90. Uterine contractions were present but the fetal heart could not be heard. There was no discharge of blood or amniotic fluid. At 3:45 a.m. pains were harder, and a moderate amount of bloody discharge was present. At 5:00 a.m. bleeding was considerable in amount, the uterus was tender between contractions, and pain was continuously present. Her facies was pale and anxious, and her pulse was 100. Antepartum separation of the placenta was diagnosed. The membranes were ruptured artificially, and at 6:00 a.m. a mid-forceps extraction of a dead baby was easily performed, this was immediately followed by expulsion of the placenta and a large amount of dark blood, both fluid and clotted. As bleeding continued following the birth of the baby and the placenta, the uterus was thoroughly packed with gauze, and 1 cc. Ergometrine given intravenously.

For a while following this treatment, bleeding seemed under control, but the uterus did not contract satisfactorily, and by 7:35 a.m. she was bleeding through the packing, and the uterine fundus felt extremely boggy. At this time she showed signs of shock, with marked pallor and restlessness, a pulse of 150, and a blood pressure of 70.

systolic Morphine (1/6 gr) and Pituitrin (1 cc) were given hypodermically, the foot of the bed was raised, she was grouped for transfusion, and salt solution was started by the intravenous route running slowly so that she had 2,000 cc in one hour. At 8.30 a m her condition was unimproved, the vaginal flow was pinkish instead of red, but still continuous. Transfusion of 500 cc of citrated blood was given, followed by continuous, slow intravenous salt solution. Morphine (1/6 gr) hypodermically was again necessary. An improvement in color and pulse followed the transfusion, the pulse dropping to 128. For a while she rested peacefully. At 9.15 a m steady flowing again showed, this time it was bright red. She again became very pale, and the pulse became thready and uncountable.

It was apparent that the uterus did not have the power of contracting sufficiently to stop the bleeding and that she would die from hemorrhage unless it was checked. Hysterectomy was the only measure available, although it seemed impossible for her to stand the shock of operation. It was determined, however, to take the risk of operative shock, as it seemed her only chance of recovery.

At 10.00 a m another transfusion of 500 cc of citrated blood was started, the uterine packs were removed, and a supravaginal hysterectomy was performed under light ether anesthesia. The uterus was bluish black throughout most of its external surface, and the coloring extended into both broad ligaments and down onto the bladder peritoneum. On cutting the uterus, the entire wall was invaded by dark blood over a large part of the anterior and posterior uterine walls. Slow administration of intravenous salt solution followed the transfusion. Her color and pulse again improved during transfusion, the pulse dropping to 140, the blood pressure was 80 systolic. She was returned to bed with a pulse of 130 and a blood pressure reaching 100 systolic, 60 diastolic. Salt solution (1000 cc.) was given.

Recovery from the shock of hemorrhage and operation was fairly good. She showed a hemoglobin percentage of 45 on the following day and was given another transfusion of 500 cc of citrated blood. She took fluids well, but it was noticed that in the next few days her urinary output was very small. A catheter specimen of urine on July 29 showed a specific gravity of 1.009, a slight trace of albumin, no sugar and a sediment containing many red blood cells, an occasional white-blood cell and a few granular casts. The plasma protein of her blood was below the critical level of 5 gm per cent. Her blood pressure varied from 120 to 150 systolic, 70 to 80 diastolic. Her pulse ranged

from 80 to 100, and her temperature from 99 to 100°F. On July 29 she was given 300 cc of citrated blood, and her intake of fluid was decreased on account of the low blood protein and the small amount of urine.

On July 30 she seemed stronger, her intake and output of fluids were more nearly balanced. She showed no signs of edema and no rales in the lungs but had headache at times.

On July 31 she complained of severe headache, dizziness and epigastric pain, her blood pressure was 165 systolic and 80 diastolic. In the late afternoon she became confused, and had convulsive movements of her right arm and both legs with a generalized convulsion lasting five minutes, following which she was perfectly conscious. During the night she had six similar convulsions with partial consciousness between. There was no paralysis or disturbance of reflexes between convulsions. Her blood pressure varied from 150 to 180 systolic, 90 to 105 diastolic. She voided 450 cc. of urine showing a little albumin, many blood cells and a few granular casts. Her retinas showed no exudate, hemorrhage or abnormality of the arteries.

Treatment during the convulsive period consisted of morphine once, followed by magnesium sulfate (20 per cent) subcutaneously, in 10 cc doses intravenously at three-hour intervals for three doses. Lumbar puncture was done, dropping the spinal fluid pressure from 250 to 150 mm of water. This fluid showed no abnormalities. She was also given 100 cc of 50 per cent glucose intravenously twice.

On the following morning she was conscious and somewhat nervous but had no more convulsions. Her urine amounted to 20 cc., with findings as before, her blood pressure was 140 systolic, 70 diastolic. The blood urea nitrogen was 70 mg per cent.

Daily thereafter she showed steady improvement, passing normal amounts of urine and with a blood pressure varying from 145 to 160 systolic, 90 to 100 diastolic. On August 10 her blood urea nitrogen was 42 mg and her hemoglobin 55 per cent. She made a normal surgical convalescence from her laparotomy. She was discharged home with instructions to rest in bed, take iron and follow a low-protein diet. Her urine at this time showed a specific gravity of 1.005, no albumin or sugar, and nothing in the sediment.

On November 4, several months after labor and operation, she was seen at the clinic with the following results: her hemoglobin was 90 per cent, her blood pressure 164 systolic, 110 diastolic, heart normal, blood urea nitrogen 25 mg per cent, phenolsulfonphthalein 45 per cent in two hours.

Her catheterized urine showed a specific gravity, after fluid restriction, of 1 008, no albumin or sugar, and a sediment containing about 10 red-blood cells and leukocytes per high power field. Her retinas showed no exudate or narrowing of the arteries. Her general condition was very satisfactory.

Comment In reviewing the case, several important facts are evident.

There was a failure in prenatal treatment, in that following the discovery of hypertension she did not have careful enough treatment. She should have entered the hospital or at least have been seen more frequently.

Very extensive hemorrhage both into the uterine cavity and into the uterine musculature was present, and as a result, the uterine musculature lost its power of contracting so that bleeding did not cease with the birth of the child or with careful packing of the uterine cavity.

Thorough and persistent administration of intravenous salt solution and blood undoubtedly saved her from death and enabled her to stand the shock of hemorrhage and hysterectomy, the latter being the only measure effective in checking the bleeding.

The late occurrence of convulsions, associated with a high degree of uremia, suggests the presence of chronic nephritis, with the uremia possibly precipitated by the previous hemorrhage or treatment. The subsequent final examination confirms the opinion that she had an underlying chronic nephritis, the exact type of which still remains in doubt.

NOTICE TO FELLOWS OF THE MASSACHUSETTS MEDICAL SOCIETY

THE *New England Journal of Medicine* is sent to all fellows whose dues are fully paid. After March 1, delinquent fellows are dropped from the mailing list. All fellows are urged to remit their dues for the current year to their district treasurers before March 1.

CHARLES S. BUTLER, M.D., *Treasurer*

MEDICAL POSTGRADUATE EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau, have been arranged for the week beginning February 21.

BRISTOL NORTH

Thursday, February 24, at 4 00 p. m., at the Morton Hospital, Taunton. Subject: Pneumococcus Pneumonia and Serum Therapy. Instructor:

Frederick T. Lord. Arthur R. Crandell, *Chairman*

BRISTOL SOUTH (New Bedford Section)

Friday, February 25, at 4 00 p. m., at St. Luke's Hospital, New Bedford. Subject: Complications in Obstetrics Illustrated by Case Histories. Instructor: Raymond S. Titus. Robert H. Goodwin and Howard P. Sawyer, *Chairmen*.

ESSEX SOUTH

Course omitted this week on account of Washington's Birthday.

MIDDLESEX EAST

Course omitted this week on account of Washington's Birthday.

MIDDLESEX NORTH

Friday, February 25, at 7 00 p. m., at St. John's Hospital, Lowell. Subject: Gonorrhea in the Male. Instructor: Oscar F. Cox, Jr. William S. Lawler, *Chairman*.

NORFOLK

Friday, February 25, at 8 30 p. m., at the Norwood Hospital, Norwood. Subject: Bleeding in the Last Trimester of Pregnancy. Instructor: Raymond S. Titus. Hugo B. C. Riemer, *Chairman*.

NORFOLK SOUTH

Monday, February 21, at 8 30 p. m., at the Quincy City Hospital, Quincy. Subject: The Use and Misuse of Prontylin. Instructor: R. Cannon Eley. David L. Belding, *Chairman*.

PLYMOUTH

Course omitted this week on account of Washington's Birthday.

WORCESTER (Milford Section)

Thursday, February 24, at 8 30 p. m., in the Nurses Home of the Milford Hospital, Milford. Subject: Drug Therapy in Pediatrics. Instructor: Eli C. Romberg. Joseph Ashkins, *Chairman*.

WORCESTER NORTH

Friday, February 25, at 4 30 p. m., at the Burbank Hospital, Fitchburg. Subject: The Use and Misuse of Prontylin. Instructor: Benjamin W. Carey, Jr. Edward A. Adams, *Chairman*.

MISCELLANY

OPPORTUNITY FOR PHYSICIANS TO TOUR AMERICA EN ROUTE TO THE SAN FRANCISCO MEETING

The thought that the forthcoming American Medical Association session in San Francisco, June 13 to 17, is such a splendid opportunity for a tour of the United States, both going out and coming back, has inspired definite action. The co-operation of more than twenty-five state medical societies has made it possible to arrange a special train tour which will include such outstanding high lights of the North American continent as the Indian Detour, the Grand Canyon, Los Angeles, Riverside and Santa Catalina Island—on the way out to San Francisco. A choice of two return routes is possible, one of which

visits the charming cities of Portland, Seattle, Victoria and Vancouver and the beautiful scenic spots of the Canadian Rockies, the second route travels via Yellowstone National Park, Salt Lake City, Royal Gorge, Colorado Springs and Denver.

There is an all inclusive price for this tour which includes transportation from home town to home town though the tour starts officially at Chicago on Monday, June 6, from which point an American Express escort joins the group, as this travel company has been appointed transportation agent and the business details of the trip are in its capable hands.

Let us take a preview of the tour. The first day out of Chicago, racing across the broad wheat growing face of Kansas, we become acquainted with our traveling companions, physicians from other states, their families and friends and find ourselves among congenial, like minded people. We first leave our train at Lamy, New Mexico to enter the Indian pueblo district by motor coach. We spend a whole day exploring the traces left by a vanished civilization on this continent, visiting Santa Fe, Tesuque, Puye and Santa Clara Pueblo.

The next morning's arrival at the Grand Canyon will remain in our memories forever. The vast chasm, from four to eighteen miles wide from rim to rim, gives us stupendous vistas of awe inspiring beauty, unparalleled the world over. We drive over the famous Hermit Rim Road, skirting the edge of the chasm in the morning, and in the afternoon over the Desert View Road through the Tusayan National Forest and along the canyon's rim, stopping at Yavapai Point Observation Station for a short, interesting lecture by the park naturalist. This drive ends at the Watch Tower, a re-creation of the ancient towers erected by the prehistoric inhabitants of the Southwest.

The amazing city of Los Angeles is next on our itinerary, and our sightseeing trips acquaint us with its Spanish quarter and Chinatown, as well as its beautiful environs, including flowering Pasadena, Riverside, with its orange empire, lemon and grapefruit orchards, and famous Mission Inn, is another destination, and then, on our third day in California, we sail to beautiful Santa Catalina Island, playground of this land of the sun. And in this delightful manner, a week after leaving Chicago, we arrive at San Francisco in time for the meeting. We shall not discuss the interesting time that awaits us at our conclaves, as the object of this article is to describe the pre and postconvention tour. So we consider our return itinerary.

Supposing we had chosen Return Route No. 1. We shall visit Portland, Oregon, famed as the City of Roses and enjoy a drive along the noted Columbia River Highway. Seattle is next, and here we also cover all the points of interest, including both the lake and sound districts. Now the Canadian part of our journey begins, we sail by comfortable steamer to the cities of Victoria and Vancouver, where we do sightseeing. Now a train takes us into the enchanting scenic region of the Canadian Rockies and we stop at Chateau Lake Louise, at the lake of the same name—a gem of exquisite color, surrounded by green forests and snowy peaks. Our drives through the heart of the Rockies take us to Moraine Lake, the Valley of Ten Peaks, Johnson Canyon and finally to Banff, where we make another stopover. After additional sightseeing around Banff, we entrain for Chicago.

Return Route No. 2 takes us to Chicago in a more southerly route. A three-and-a-half-day tour of Yellowstone National Park is one of the high lights of this tour. Ranger naturalists conduct our party to the geysers and

hot pools, and we feast our eyes on Old Faithful in its hourly eruption. We also see the Grand Canyon of the Yellowstone and Mammoth Hot Springs. Salt Lake City is on our itinerary, which gives us an opportunity to visit Saltair Beach on Great Salt Lake, also the great copper mills and smelters. Our next call is at Colorado Springs, the noted health and pleasure resort. Our travels in the Rockies take us up to the summit of Pikes Peak, to the Garden of the Gods, to Seven Falls, and finally to Denver. This lovely city is a center for outings in the Rockies, and we are soon off on a sixty five mile tour of Denver mountain parks, including the memorial museum and tomb of Buffalo Bill of western fame. From Denver we travel to Chicago.

The above is barely a glimpse of the outline of the tours, but it is hoped that some idea has been given of the enjoyable travel awaiting those physicians and their families and friends, who wish to combine attendance at the meeting with an interesting journey and a happy vacation.

PRIZE SUBSCRIPTION

The *Journal* is offering a prize subscription for one year to the undergraduate contributing the best original article to the *Tufts College School of Medicine Medical Journal* during the current year. The award will be made annually. The editorial staff of the *Journal* will make the final selection from three papers recommended by the Tufts faculty advisers.

CORRESPONDENCE

SUGGESTED INSTRUCTIONS CONCERNING THE USE OF SULFANILAMIDE

To the Editor—Some time ago three members of the hospital staff were requested by the General Executive Committee of the Massachusetts General Hospital to submit suggestions concerning the use of sulfanilamide. Their report was so comprehensive and clear that copies were made and forwarded to all staff members. A copy is enclosed in the hope that it may be of interest and value to readers of the *Journal*.

N. W. FAXON, M.D., *Director*
Massachusetts General Hospital,
Boston

* * *

- I *Drugs to be used*—Sulfanilamide (Merck)
Prontylin (Winthrop Chemical Company)
Prontosil (Winthrop Chemical Company), rarely
- II *Diseases in which it should be employed*
 - 1 Gonococcal infections, particularly arthritis
 - 2 Meningococcal infections, particularly meningitis
 - 3 Acute or subacute infections due to beta hemolytic streptococci.
 - 4 The drug is still to be regarded as under trial for Type III pneumococcus, *B. coli*, *B. proteus*, *B. welchii* and *B. typhosus*.

Whether or not all cases of chronic prostatitis due to the gonococcus can be cared for with sulfanilamide remains to be seen. We have observed a few failures. They may represent inadequate therapy. Time will tell.

- III *Dosage*—Until we have further information concerning the smallest amount of the drug necessary to cure any of the above mentioned infections, it would seem wisest to prescribe the

drug in full doses. Full doses are calculated as follows: $\frac{3}{4}$ gr per pound of body weight, not exceeding 120 gr in any 24 hour period. The exact length of time such treatment must be continued is unknown, probably 1 or 2 weeks of such therapy is adequate.

IV Method of giving It is preferable to administer the drug by mouth. The daily calculated dose should be subdivided into four or six equal parts and given at 6- or 4 hour intervals. In rare instances, when the patient seems to be in immediate danger of death, it may be advisable to give the full dose at once, or half the full dose at the beginning of treatment and the other half 4 hours later. The patient should then go on to a fourth and sixth of the full dose at 6- or 4 hour intervals.

Sodium bicarbonate may be given in equal doses with each dose of sulfanilamide, if desired. The soda has no known effect upon the pharmacologic action of the drug and may allay the severity of the gastric symptoms and prevent the acidosis attendant upon the use of sulfanilamide.

If the patient is vomiting, a 0.6% solution of sulfanilamide (Merck) in saline may be auto-claved and given subcutaneously as a clysis, or if desired, Prontosil may be injected intramuscularly.

V Suggested laboratory studies

- 1 A complete blood examination should be done before starting the drug and should be repeated every 3 to 7 days.
- 2 If there is any question of renal impairment or of acidosis, nonprotein nitrogen, chloride and carbon-dioxide-combining power determinations should be done on blood samples and should be repeated, as seems indicated, in order to evaluate renal function and the degree of acidosis.
- 3 Blood sulfanilamide determinations are not absolutely necessary. The maximum blood value is probably attained between 24 and 72 hours after the institution of therapy. Therefore, such a determination made during this period and repeated occasionally should give one an excellent idea as to the existing blood concentration. From the data at hand, it would appear that the blood level should be maintained at 5 mg per 100 cc. or above. On full doses, most patients vary between 8 and 15 mg free sulfanilamide per 100 cc. of blood. Excessive fluid intakes tend to decrease the blood sulfanilamide level, and therefore it is probably wise not to administer fluids excessively, a total 24 hour fluid intake of from 2000 to 3000 cc would seem adequate.

VI Contraindications

- 1 Severe anemia and leukopenia
- 2 Marked renal impairment.
- 3 Obstructive jaundice.

VII Incompatible drugs No type of sulfate medication, such as magnesium sulfate, ferrous sulfate, and so forth, should be administered during the time the patient is receiving sulfanilamide because it increases the incidence of sulfhemoglobinemia.

VIII Complications

- 1 Cyanosis. Sulfhemoglobinemia is the most frequent cause, but actual discoloration of the cells may account in part for the cyanosis.
- 2 A moderate acidosis is encountered in a fair number of the patients receiving the drug, rarely does the carbon-dioxide-combining power of the blood drop below 40 vol. per cent.
- 3 Gastric symptoms are frequent, although rarely severe. They usually consist of nausea and loss of appetite, vomiting is occasionally encountered.
- 4 Various skin eruptions as well as urticaria have been encountered. The exact manner in which these are produced is unknown. When present, the drug should probably be discontinued.
- 5 Sustained fever as high as 103 or 104°F may be encountered during the administration of the drug. It disappears promptly on discontinuance of it.
- 6 Hemolytic anemia has been observed. Anemia is frequently encountered, and varying grades of leukopenia have been seen. The leukopenia may appear after the discontinuance of the drug.
Severe anemia is a contraindication to further use of the drug.
- 7 A rising blood nonprotein nitrogen should be considered as a possible contraindication to further use of the drug.

RECENT DEATH

HOPKINS — BERTRAND H. HOPKINS, M.D., of 24 Wash-
ington Street, Ayer, Massachusetts, died August 13, 1937
He was in his fifty sixth year
Dr Hopkins received his degree from Tufts College
Medical School in 1897
He was a fellow of the Massachusetts Medical Society
and a member of the American Medical Association

REPORT OF MEETING

BOSTON UNIVERSITY MEDICAL SOCIETY
"Observations on the Diagnosis and Treatment of Brain
Tumors" was the subject of an address given by Dr Gil-
bert Horrax of the Lahey Clinic before the monthly meet-
ing of the Boston University Medical Society on February
7 in the Evans Memorial Auditorium. Dr Reginald Fitz
presided at the meeting
The student officers of the society are president, Rob-
ert E. Moss, Boston, vice president, John P. Rattigan,
Hyde Park, corresponding secretary, Timothy L. Curren,
Dorchester, secretary, Marion V. Zottoli, Dorchester, re-
gional delegates, Nicholas Fiumara, Boston, Deborah V.
Rubenstein, Roxbury, and Frederick J. Fagan, Norwich.
Connecticut forum committee, Sidney Gohn, New York
City, Morris Taylor, Chelsea, John Dougherty, Bath, Maine,
Iver S. Ravin, Brookline, and Isabel S. Money, Mattapan

UNITED STATES CIVIL SERVICE
EXAMINATION
Physiotherapy Aide, \$1,800 a Year
Applications must be on file with the United States
Civil Service Commission at Washington, D. C., not later
than March 7

Applicants must have been graduated from a school of
physiotherapy meeting the standards established by the
American Medical Association, or they must have had at
least eighteen months experience as classified pupil aides
in physiotherapy in a Veterans Administration facility

CARNEY HOSPITAL

The monthly clinical meeting and luncheon of the Car-
ney Hospital staff will be held on Monday, February 21,
at 11:30 a. m., in the Andrew Carney Assembly Hall

PROGRAM

Case Report: Compound fracture of skull with convulsions,
decompression and recovery. Dr. W. E. Browne.
Pathology Exhibit.
Fluid Balance. Dr. T. J. P. Lyons.
Discussion by Dr. N. A. Welch, Dr. C. A. Robinson and
Dr. John Thornton
Physicians and medical students are cordially invited to
attend.
R. J. HEFFERNAN, M.D., *Secretary*

NORFOLK DISTRICT MEDICAL SOCIETY

The next regular meeting of the Norfolk District Medi-
cal Society will be held in the Beth Israel Hospital, on
Wednesday evening, February 23, at 8:15

PROGRAM

Business
Communication: Dermatitis venenata due to cosmetic and
industrial irritants. Dr. John G. Downing. Discus-
sion by Dr. Francis P. McCarthy
Collation
FRANK S. CRICKSHANK, M.D., *Secretary*

ROBERT B. BRIGHAM HOSPITAL

There will be an open meeting at the Robert B. Brig-
ham Hospital, 125 Parker Hill Avenue, Boston, on Thurs-
day evening, February 24, at 8:15. Dr. Maurice B.
Strauss will speak on "Vitamin Deficiencies."
Doctors and medical students are cordially invited to
attend.
ROBERT SANDERSON, M.D., *Secretary*

TRUDEAU SOCIETY

The next meeting of the Trudeau Society will be held
in the auditorium of the Beth Israel Hospital on February
24 at 8:15 p. m. Dr. Everts A. Graham, editor of the
Journal of Thoracic Surgery and professor of surgery at
Washington University School of Medicine, will speak on
"The Problem of Bronchiogenic Carcinoma." The paper
will be discussed by Dr. Edward D. Churchill and Dr.
Richard H. Overholt.
MOSES J. STONE, M.D., *Secretary*

BOSTON MEDICAL HISTORY CLUB

There will be a meeting of the Boston Medical History
Club at the Boston Medical Library, 8 Fenway, Boston,
on Wednesday, February 23, at 8:15 p. m.
Dr. Chester M. Jones will speak on "The Development
of Our Knowledge of the Gastrointestinal Tract and Its
Diseases."
BENJAMIN SPECTOR, M.D., *Secretary*

NEW ENGLAND SOCIETY OF PSYCHIATRY

The annual spring meeting of the New England Society of Psychiatry will be held at the Neuro-Psychiatric Institute of the Hartford Retreat, Hartford, Connecticut, on April 26

GEORGE A ELLIOTT, M.D, *Secretary Treasurer*

BOSTON SOCIETY FOR THE ADVANCEMENT FOR GASTROENTEROLOGY

The Boston Society for the Advancement of Gastroenterology will hold a meeting in the amphitheater of the new surgical building of the Boston City Hospital, on Thursday, February 24, at 12 o'clock noon Dr Maurice Binet will lecture on "Liver Deficiencies" Dr Binet is chief physician at Vichy and a medical doctor at the Faculty of Paris

C. W McCLURE, M.D, *Secretary*

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY, FEBRUARY 21

MONDAY FEBRUARY 21

- *11:30 a m Carney Hospital monthly clinical meeting and luncheon Andrew Carney Assembly Hall

WEDNESDAY FEBRUARY 23

- *9 10 a m Boston Dispensary Hospital case presentation Dr S J Thannhauser
- *12 m. Clinicopathological conference. Children's Hospital Amphitheater
- 8 15 p m Norfolk District Medical Society Beth Israel Hospital Boston
- 8 15 p m Boston Medical History Club Boston Medical Library 8 Fenway

THURSDAY FEBRUARY 24

- 8:30-9:30 a m. Exchange visit surgical and orthopedic staffs of the Peter Bent Brigham and Children's hospitals held this week at the Peter Bent Brigham Hospital
- *9 10 a m Boston Dispensary Gastrointestinal clinic Dr h S Andrews
- 12 m. Boston Society for the Advancement of Gastroenterology Boston City Hospital Amphitheater of the new surgical building
- 8 15 p m Trudeau Society Beth Israel Hospital auditorium Boston.
- *8 15 p m Robert B Brigham Hospital 125 Parker Hill Avenue Boston.

FRIDAY FEBRUARY 25

- *9 10 a m Boston Dispensary The Diagnosis of Multiple Myeloma Dr Bernard Jacobson
- 10 a m 12 30 p m Tumor clinic Boston Dispensary
- 8 p m Massachusetts Psychiatric Society Boston Psychopathic Hospital

SATURDAY FEBRUARY 26

- *9 10 a m Boston Dispensary Hospital case presentation Dr S J Thannhauser
- 10 a m 12 m Staff rounds at the Peter Bent Brigham Hospital Conducted by Dr Henry A Christian

SUNDAY FEBRUARY 27

- 4 p m Illustrated public health lecture Faulkner Hospital auditorium Backache Dr John D Adams
- 4 p m Free public lecture Harvard Medical School amphitheater of Building D Pain in the Abdomen Dr Channing Frothingham and Dr Richard H Miller

Love and Happiness Intimate problems of the modern woman 1 M. Hotep 235 pp New York and London Alfred A. Knopf, 1938 \$2.00

Fever Therapy Abstracts and discussions of papers presented at the First International Conference on Fever Therapy, March 29, 30, 31, 1937 Walter M. Simpson, William Bierman, et al 486 pp New York Paul B Hoeber, Inc., 1937 \$5.00

BOOK REVIEWS

4 *Bibliography of the Works of Ambroise Paré Premier Chirurgien & Conseiller du Roy* Janet Doe. 266 pp Chicago The University of Chicago Press, 1937 \$5.00

Miss Doe has written a very valuable book. It is much more than a bibliography, for she has listed with extraordinary accuracy not only every known edition of Paré's works, but, in describing these books, she has added notes of unusual value on the author's life and on the times. She points out, for instance, that Paré was a man of great versatility, that he began as an unlearned barber surgeon and rose to be the idol of the army surgeons of France, and surgeon to the French kings for nearly forty years. Although he is best known for his rejection of boiling oil for the treatment of wounds and the use of the ligature and of podalic version, he is equally the epitome of Renaissance surgery, for in his simple and kindly manner, in spite of his being at times vain and ambitious, Paré brought common sense to surgery and took away from it the muddy thinking of the Middle Ages. Although at first unlearned as a writer, his style grew with him, and his later books, published after 1560, were well written. Miss Doe writes that his realistic story of the siege of Metz can fearlessly be compared with the greatest narratives of history. The golden thread running through it all is the personality of the author. Much of interest in regard to the man will therefore be found in this splendid book.

The bibliography is unusually complete. Miss Doe has searched for copies of the various editions and works in libraries throughout the world with unusual pertinacity. She has also ascertained the number of copies in the hands of private collectors. Foremost among these is Dr Harvey Cushing, whose unusual collection was used as the basis for most of the descriptions written by Miss Doe. Each book is described in complete detail and in most cases the title page is reproduced, the copies used are indicated and also the number and location of all copies found. There is little to criticize in this splendid piece of research, the result of many years of effort by an extremely conscientious individual. Unfortunately, the faults, if any, fall upon the press. Much of the type is badly chosen, and the title pages are poorly reproduced. There are a number of criticisms in regard to the bibliographical style used by the author, but these are minor and relatively unimportant. With such splendid examples before her as the bibliographies issued in recent years by Geoffrey Keynes, particularly those of William Harvey and Sir Thomas Browne, it seems a little unfortunate that Miss Doe did not follow in detail the style set by her predecessor. In spite of these criticisms, which must be acknowledged as being definitely minor, except for the printing, the book is one of the outstanding bibliographies of our time and as such sets a standard that few will equal and practically none surpass.

Genital Abnormalities, Hermaphroditism, and Related Adrenal Diseases Hugh H. Young 649 pp Baltimore The Williams & Wilkins Co., 1937 \$10.00

This is an extraordinary book. Written by the author of one of the best textbooks of urology, it represents another outstanding achievement by Dr Young. Over five hundred original drawings by Mr William P. Didusch make this volume one of the best illustrated medical works we have seen.

Fifty three personal cases form a unique collection of genital abnormalities and dysfunctions of the most unusual kinds. These rare anomalies are described as hermaphroditism, male and female pseudohermaphroditism, hermaphroditism verus, and adrenogenital syndrome, and the more common genital abnormalities such as hypospadias, epispadias, cryptorchidism, and, so forth. The embryology of hermaphroditism is well described with clear diagrams and illustrations. This astonishing array of cases is illustrated by photographs and drawings, many of which were made at the operating table. Each step in the operating technic is portrayed clearly enough to aid anyone who attempts such surgery.

The anguish of the unfortunate individuals described by Dr Young can be imagined. Boys have been brought up as girls only to discover that they had been wrongly classed sexually, or were of indeterminate sex. One patient was brought up in a male orphanage until operation disclosed a uterus, tube and ovary. The child was then dressed as a girl and transferred to a female orphanage. At the age of seventeen a hernia operation revealed that the supposed ovary was a testicle, and the patient again assumed male attire. Such are the tragedies Dr Young has described. As a master craftsman he has righted the wrongs of nature by the many ingenious and original operative procedures, which he has so ably described in this book.

Minor Maladies and Their Treatment. Leonard Williams. Seventh edition. 439 pp Baltimore William Wood & Co., 1937 \$3.75

The author of this work gives as its *raison d'être* the fact that when he went into practice he found himself moderately well equipped in the diagnosis and treatment of the diseases which he most seldom encountered, but ignorant in those matters about which he was frequently consulted. So this book is devoted to a discussion of such subjects as colds, coughs, sore throats, indigestion, constipation, neuralgia and headache. The author writes in a simple, conversational style and adds bits of experiences acquired through years of practice, still, it is rather surprising that a work like this has gone on to the seventh edition.

4 *Primer for Diabetic Patients An outline of treatment for diabetes with diet, insulin and protamine zinc insulin including directions and charts for the use of physicians in planning diet prescriptions* Russell M. Wilder Sixth edition reset. 191 pp Philadelphia and London W B Saunders Company, 1937 \$1.75

This new edition of Dr Wilder's book was made necessary by the addition of protamine insulin in diabetic treatment. In the nine sections are given, in the simplest and most direct language, discussions of the nature of diabetes and its treatment by diet and insulin. Various important complications of diabetes, including a brief section on the hygiene of the feet, are given adequate space as well as special dietary problems for children and for weight reduction.

A Monograph on Veins Kenneth J Franklin 410 pp
Springfield and Baltimore Charles C Thomas, 1937
\$6 00

Dr Franklin has long been a leader in investigation of the anatomy and physiology of the veins. His book is the culmination of many years of intensive work and brings together not only his own extensive experiences but also a complete review of the entire subject, a summary that is not to be found between the covers of any other volume. Known also for his interest in the history of medicine, there is a distinct historical trend to be noted on almost every page. Although perhaps primarily a book for the physiologist who is working on the functions of the veins, there is much material here that will interest the clinician who is actively interested in keeping in the front rank of research. The surgeon and the neurologist, moreover, will find much of value. The book, published in a sumptuous fashion, with excellent illustrations and replete with historical data, becomes a valuable part of the medical historian's library. Unique in character, reflecting sound research, this volume should have a wide appeal to the medical profession.

A Text-Book of Ophthalmic Operations Harold Grimsdale and Elmore Brewerton Third edition. 322 pp
Baltimore William Wood & Co, 1937 \$6 00

This well written third edition, containing 105 line drawings, constitutes an excellent manual for current practice in ophthalmic surgery. The first seven chapters deal with surgery of the ocular adnexa (muscles, eye lids, conjunctiva, lacrimal apparatus), including enucleation, and the remaining five chapters, comprising about one half the text, deal with surgery upon the eye itself (cataract, glaucoma, detached retina and intraocular foreign bodies).

If one comment were allowed for improvement in the text, it would seem to take the direction of a condensation of items of purely historical interest, and an elaboration of items in the last five chapters dealing with preoperative and postoperative care. For example, the utilization of bionicroscopy preoperatively and postoperatively and the interpretation of surgical complications in terms of tissue pathology would seem to add greatly to the usefulness of the text.

The Postmortem Examination Sidney Farber 201 pp
Springfield, Illinois, and Baltimore Charles C Thomas, 1937 \$3 50

This is a scholarly piece of work which can be highly recommended. The book begins with a historical introduction, deals with the signs of death, the equipment for autopsy technic and care of bodies, the regulations governing postmortem examinations, the procedure of viewing a body, the removal of organs, their section, the examination of the skeleton, special technics including a short summary of medicolegal procedures, a chapter on postmortem examination in infants and children with appendices giving the weights of organs, the standard procedure for postmortem examinations as adopted by pathologists and undertakers in New York City and, finally, a copy of a typical autopsy protocol by Virchow.

There are minor faults, such as the implication that in adults the rib cartilages can be readily sectioned by a knife and the indication that removal of the organs of the neck is a standard and usual procedure in autopsy technic. However, these are of slight importance in a book which is remarkable for its thoroughness, its documentation with good bibliographies, and the practical character of its instruction.

The Traffic in Health Charles Solomon 393 pp New York Navarre Publishing Company, Inc., 1937 \$2.75.

This book is put out with a gaudy jacket showing the silhouette of a cloaked skeleton holding a bottle which is surrounded by an effulgence which might be mistaken for a halo. It is extremely timely and is a mine of information. Unfortunately, the writing is dull and in catalogue fashion, classified according to the ailments which drugs are supposed to benefit. Many interesting facts are obtained by a study of this volume, all of them pointing to the great necessity of a revision of our laws to protect the public. Even though the reviewer has been in touch with this field for years, he found many new facts recorded in this book. It is worth the perusal of every physician in order that he may aid in the appropriate education of his patients and guard them from the unscrupulous manufacturers of patent medicines.

Materia Medica, Pharmacology, Therapeutics and Prescription Writing For students and practitioners Walter Arthur Bastedo Fourth edition, reset. 778 pp Philadelphia and London W B Saunders Company, 1937 \$6.50

This is a new edition of a standard text brought well up-to-date, including even the recent work on sulfanilamide. The present edition follows the previous ones, and like all pharmacological texts, studies the complete action of each drug, grouping the various drugs according to their customary use or chief action in treatment. The therapeutic discussion is more extensive than in most English texts and is on the whole satisfactory though some of the recommendations would be disapproved in ultra-scientific clinics. The discussion of flavoring and prescription writing is unusually clear.

The Endocrines in Theory and Practice Articles republished from the *British Medical Journal* 278 pp Philadelphia P Blakiston's Son & Co, Inc., 1937 \$3.50

This book is a joint effort by the English workers in endocrinology to fill the crying need for something which the general practitioner can turn to in order to keep up-to-date in this field. It corresponds in many respects to *Glandular Physiology and Therapy*, published in 1935 by the American Medical Association, which comprised a series of similar articles by the American profession. The book is lucid, up-to-date, accurate, and not too comprehensive. Its list of authors includes the names of many who have contributed widely to endocrinology. It should be a valuable asset to anybody interested in this field.

The Baby's First Two Years Richard M. Smith 121 pp Boston Houghton Mifflin Company, 1937 \$1.75

For more than two decades Dr Smith's manual on infant care has been widely and favorably known in these parts. In many households it has been, so to speak, standard. And indeed it answers most of the questions concerning feeding, habits and general management which are likely to arise in the normal course of events. Its aim is to supplement, not to supplant, personal advice from the physician. For this latest edition the subject matter has been revised or entirely rewritten to accord with the most recent accepted opinion. Safe, sane and authoritative, this little book of reference can be enthusiastically recommended to anyone who is charged with the care of a baby.

NUMBER 8

THE DEVELOPMENT OF MEDICINE AND ITS TRENDS IN THE UNITED STATES, 1636-1936

HENRY E. SIZERIST, M.D.*

BALTIMORE

IT IS indeed a pleasure and privilege to be able to participate in the tercentenary celebration of this great and beautiful city, and I am particularly pleased with the fact that the medical profession has been given such a prominent place in this celebration. A few hours ago we deposited a wreath at the grave of the first doctor whose name has been recorded in this city. This was not a mere gesture. It had a profound significance, since it showed that not only are the noted doctors who make the outstanding discoveries remembered, but the humble practitioner as well—the practitioner who puts their teachings into practice. It showed also that we medical men, wherever we may stand, are members of one family. We know little about Dr. Leonard's life and work, but we know that he was a physician, that he was one of us, serving the same ideals that we serve.

Three hundred years is a short period in history, yet what tremendous changes have been brought about during that time! Three hundred years ago came the first settlers, William Pynchon sailing up the river, landing here and founding a new Springfield, today we see a thriving city with many industries, beautiful homes, numerous hospitals, and sixteen medical organizations. Three hundred years ago in this vast country were virgin forests, prairies and deserts, all inhabited by a few Indians. Today there are highways and railroads everywhere, large cities, a highly developed industry producing forty per cent of the world's output. If there ever was an epic in the history of mankind, the conquest and the opening up of the American Continent was such an epic, infinitely more dramatic than the Trojan War.

Just as interesting as the history of the American continent is the history of American medicine. I must confess that ten years ago I knew little

about American medicine. Some of this country's outstanding contributions were known to me, as to everybody else— anesthesia, some new operations, the work of Gerhard, Nathan Smith and a few other men. I used daily the *Index Catalogue* of the Library of the Surgeon-General's Office, by far the best medical bibliography existing, that it was produced in an army office is a fact unparalleled in history. I had friends in America, among them Colonel Fielding H. Garrison, who has contributed so much to the history of medicine. The inspiration to study this history came to me from Dr. William H. Welch, who in 1927 visited me at the University of Leipzig. He told me of his plan to establish an Institute of the History of Medicine at Johns Hopkins University. He told me of his own work that is so intimately connected with half a century of American medicine, and invited me to be visiting lecturer at Johns Hopkins some day when the new institute was functioning. I had no idea at that time that I should be called to succeed Dr. Welch in the chair of the history of medicine, but I devoted a number of years reading everything on the subject I could find, and studying the books of American medical pioneers. Since then I have traveled all over this country, and my interest in American medicine has been ever increasing. Our Institute will begin publishing this year a series of reprints of American classics that should be in the hands of every doctor.

What makes the history of American medicine so fascinating is that in various periods tremendous difficulties had to be overcome— difficulties due to the size of the country, to its rapid expansion, to the general problems of colonization. We should expect that a new country would be able to take advantage of all the experiences of the older countries. The settlers who colonized America were Europeans, in full possession of the benefits of European civilization. We should expect them to have continued the cultural life of Europe at the point where they had left it. Yet we must not

Presented at the Medical Profession's Observance of the Tercentenary of the Founding of Springfield, May 18, 1936, at Springfield, Massachusetts.

William H. Welch, Professor of the History of Medicine and director of the Institute of the History of Medicine, Johns Hopkins University, Baltimore.

forget that civilization depends not only on men but also on institutions. England had its Oxford and Cambridge, and had had them since the Middle Ages. There were libraries all over Europe, and they had been there since the early Middle Ages. There are still libraries in Europe containing manuscripts written more than ten centuries ago. There were medical schools all over western Europe. And western Europe, besides, was a small territory where the young men eager to learn could easily travel from one center of learning to another. Here in America there was wilderness, hostile Nature, hostile Indians. Physicians and books were rare, and the settlers were poor. They had to start at the bottom. In three hundred years American medicine repeated the development of three thousand years of European medicine in all its phases.

If we look at conditions during the Colonial period, we find the parallelism between European and American development most strongly marked. During the early Middle Ages the medical man was as a rule a cleric, and in the same way there was a period of clerical medicine in New England. The clerics represented the educated part of the population. They were called upon to give help in the case of illness, and the chronicles have transmitted the names of quite a few of them, including Deacon Samuel Fuller, Thomas Thacher and Cotton Mather. Sometimes a governor was asked for advice in case of sickness, as is interestingly revealed, for example, in the correspondence of John Winthrop, Jr. There was a period in ancient Greece when physicians were craftsmen, educated as such by serving a master as apprentice for a number of years. At the time of the American Revolution there were about three thousand five hundred physicians in the colonies, of which not more than four hundred were graduates of universities, the others, like the disciples of Hippocrates, had been educated by serving apprenticeships with physicians, a system which undoubtedly had some advantages. While in Europe medicine and surgery were entirely different arts, often antagonistic, in America physician and surgeon were one, and even late in the nineteenth century the surgeon usually had a general practice as well.

Another parallel is to be found in the development of hospitals. The European "hospitals" in the early Middle Ages were xenodochia—guest-houses, poorhouses to provide food and shelter to the indigent. Medical treatment in such places was merely incidental. It was not until much later that true hospitals were erected. In this country as early as 1612 such a guesthouse was built in Henricopolis, Virginia. An almshouse was founded in 1732 in Philadelphia, and similar institutions

were created in New York and New Orleans in 1736. They were not hospitals in the modern sense of the word, but poorhouses similar to the old European xenodochia. The first real hospital was the Pennsylvania Hospital, which was opened in 1752, and was succeeded by the New York Hospital in 1791.

In the same way, the first medical text printed in the colonies was not a textbook but a broadside—Thomas Thacher's *A Brief Rule to Guide the Common People of New-England How to order themselves and theirs in the small pox, or measles*,—just as the incunabulum of European medicine was not a large book but a single leaf with instructions for venesection, printed in 1456.

If medicine in the early colonial days appears somewhat primitive, we must not forget that it was not on a much higher standard in Europe. What was the medical situation in 1636? Eight years had passed since Harvey had made known his discovery of the circulation of the blood. The experimental approach to medical problems had just been initiated. Less than a century had passed since Vesalius had published his seven books on the structure of the human body, laying the foundation for a new system of medicine. While science—and primarily physics and chemistry—was applied more and more to the solution of biological problems in the seventeenth century, a work that centered in the academies founded during the century, medical practice was then on a rather low level, and not without justification were the physicians of the time satirized by the poets. It was only from the middle of the century on, and chiefly under the influence of Thomas Sydenham, that the standard of practice was raised.

The development of medicine in the colonies was perfectly sound. Every effort was made to create institutions that would compare favorably with those in Europe. The spirit of the colonies was progressive, as is shown by the fact that inoculation for smallpox was introduced in Boston as early as 1721, before anyone had been inoculated in western Europe. The new Pennsylvania Hospital compared favorably with most of the similar European institutions. It was carefully planned, and the men responsible for this and other new hospitals went abroad to study conditions there, their reports are most revealing. They were most anxious to avoid the mistakes made abroad. The first medical school founded in this country—in Philadelphia in 1765—was better than many European ones. With Morgan, Rush, Shippen, Adam Kuhn and Bond it had a faculty of men well trained abroad and full of enthusiasm for their task. The school was not intended to replace the apprentice system, it completed the

student's medical education. A young man still went to a physician as apprentice for a number of years, and then entered medical school to integrate his knowledge and to study the theory of medicine. The hygienic movement that swept over Europe in the second half of the eighteenth century found its immediate repercussion in America where philanthropists like Benjamin Franklin and Benjamin Rush were strong supporters of such reform.

After the American Revolution medicine had to face fresh problems. The country expanded westward. The frontier became a decisive factor in American life, and was pushed forward relentlessly. The population increased very rapidly and new territories of tremendous dimensions had to be conquered and settled. We find fascinating personalities in medicine in these frontier days—men like Ephraim McDowell, who in 1809 performed the first ovariectomy in a log cabin in Kentucky, and William Beaumont, who studied the gastric juices while stationed at a frontier fort. Most impressive of all to me is Daniel Drake. Morgan, Rush, McDowell even, had been trained abroad. Daniel Drake was a pure product of the American soil. Brought up in Kentucky, and trained in Cincinnati, he had a clear vision of the future task of medicine. He recognized that the Mississippi Valley was to be the melting pot of the nation. What part was the physician to play in this development? No doubt the country would require more physicians, many more than the Eastern schools were able to train. New schools would have to be founded. Drake himself was an enthusiastic teacher. There was hardly a subject in medicine that he did not teach. Called to academic positions thirteen times, he occupied nine chairs in five medical schools, and founded two schools. Drake then visualized another serious task. This enormous new territory that was to be a living-place for millions of people would have to be made a healthful country to live in. Sanitation, however, required knowledge, and not only medical knowledge but knowledge of the geographic, climatic, ethnologic and social conditions of the region. Drake himself undertook such a study, and his treatise on the diseases of the Mississippi Valley is one of the classics of medical literature.

This sudden development of medicine had serious drawbacks, as it prevented a gradual and normal movement. More physicians were needed, and more and more schools were created. About four hundred medical schools were founded during the nineteenth century—twenty-seven in Indiana, thirty-nine in Illinois and not less than forty-two in Missouri. It is obvious that most of these schools could not be of very high standard.

Everywhere doctors joined in the movement, rented rooms, admitted students and gave diplomas to men who had spent hardly two years in study. Still more serious was the abandonment of the apprenticeship system. The schools no longer completed the student's education, as they had done in colonial times. No wonder that the standards of these hurriedly trained physicians were low. There were some distinguished doctors in this period, as there had been before, but the average physician was poorly prepared. At the time of the Civil War, when in Europe medicine was progressing with gigantic strides, medical conditions in America were chaotic.

After the Civil War a readjustment took place. This was a slow process, entailing endless difficulties. American society was busy developing material resources, building up industries, improving the standard of living. Science pursued for science's sake found little response. In 1876 John Billings wrote "Culture, to flourish, requires appreciation and sympathy, to such an extent, at least, that its utterances shall not seem to its audience as if in an unknown tongue."

The readjustment came from three different sources—the medical profession, the state medical societies and the medical schools. The profession as such felt that conditions must be changed if the profession was to have a respected place in society. As early as 1845 the Medical Society of the State of New York invited every medical society and school of medicine in the Union to send delegates to a general congress of physicians to be held in New York, at which ways and means of improving conditions in medicine were to be discussed. Another congress was held the following year in Philadelphia, and led to the foundation of the American Medical Association in 1847. Resolutions were passed but nothing was achieved. The Civil War interrupted this development, but the foundation of the American Medical Association had a decided significance in providing a forum for discussion and awakening the conscience of physicians. Local societies were organized in increasing numbers, and in the readjustment after the War these societies played an important part.

Another effort to improve conditions was made by the states in requiring a state license for the practice of medicine. Recognizing that the diplomas issued by the schools had little value, the states examined candidates through their boards of registration. This was not new in American medicine, for New Jersey had required a license as early as 1772, but here again a sound development had been interrupted, and one hundred years had to elapse before the requirement of a state license became general. Texas was the first state after the War to require a license.

in 1873 Others followed in rapid succession, so that by 1895 practically all the states had laid down similar requirements

But it was not enough to postulate better standards Places had to be created for the training of fully qualified physicians This is what gave to Johns Hopkins Medical School, opened in 1893, its national significance It was founded primarily as a center of medical research, and was equipped with all the facilities required for such research The student body was small, the requirements for admittance were high, and the teaching staff included some of the best men in the nation, among them William Welch, William Osler, William Halsted, Howard Kelly, John Abel, Franklin Mall and William Howell — men who had had the best training that Europe could give, and who transplanted the spirit of the European universities to America without slavishly copying their methods They succeeded in improving upon the European systems of medicine, blending the principles of German, English and French schools in a most fortunate way Most of these men have left us today, but their spirit still lives as an inspiration to the school The example set by the Johns Hopkins Medical School was soon followed by other schools The curricula were thoroughly reorganized, and in 1901 the Rockefeller Institute for Medical Research was founded

Today medical research is carried out by thousands of young people with tremendous enthusiasm We have excellent schools, and as a result, well-trained physicians, nurses and public-health officers American medicine gave the world the public-health nurse, whose value for the people's health cannot be overestimated The standard of the hospitals was materially raised through the efforts of influential organizations like the American College of Surgeons, the American Medical Association, and others The new medical science required a new type of hospital, serving not only the indigent sick but all classes of the population It is no exaggeration to state that American medicine today is without doubt the best-equipped in the world

Does this mean that all problems have been solved, that we can look back on the past with self-satisfaction? By no means, on the contrary, it seems to me that in our day a new frontier has opened up and must be settled We have all the equipment that we can wish for, our problem is to apply it so as to benefit the entire population

As we have seen, the whole development was

chaotic and unplanned, one result was that the number of physicians increased tremendously, so that we now have one for every 760 inhabitants Have we too many? I do not think so, for medicine has many more tasks to solve than it ever had before If it has had a distinguished past, it has a still more distinguished future Public health has developed very rapidly, assuming more and more tasks, and coming ever nearer to the individual The physician's expert advice is sought in education, in the prevention of crime, in the enforcement of law Serious public-health problems have been solved Spectacular diseases like plague, yellow fever, smallpox and typhus have been overcome, but there are still tuberculosis and the venereal diseases, the hygienic problems of housing and nutrition remain unsolved Hygiene and public health had to overcome great difficulties in this country, owing to its size and to its heterogeneous population, but they could build upon the solid foundation of a rational philosophy, and a democratic political organization in which the welfare of the individual has extreme weight

We have to realize that conditions are very different from what they were half a century ago Medical science has become extremely technical and specialized As a result, medical service has become increasingly expensive At the same time, the structure of society has undergone profound changes The frontier has come to an end, and immigration has virtually stopped, so that American society, formerly in constant flux, has become stabilized A paradoxical situation is developing in that medicine through its own progress is becoming too expensive, and therefore unavailable to large sections of the population Another adjustment will have to take place This time, it is not a matter of equipment and science, but a social problem that must be solved

But I am confident that the American people will solve this problem as they have solved others For this is a wonderful country, inhabited by fine men, intelligent, hard-working, with a plentiful endowment of common sense and idealism The spirit of the men who three hundred years ago founded this city, of the men who in three hundred years have developed it to what it is today, and of the medical men who for three hundred years have devoted their lives to improving the people's health, is not dead It is alive, ready to improve conditions, to create new values, conscious both of the heritage of the past and of the tasks that lie ahead

RENAL CANCER

End Results in 105 Consecutive Cases

E. ROSS MINTZ, M.D.*

BOSTON

THIS study is a continuation of the excellent report of the end results on hypernephroma published by Smith in 1925. From the beginning of 1925 to the end of 1935, 105 patients on whom a definite diagnosis of renal cancer was made were admitted to the Massachusetts General Hospital. This series includes only those cases where the diagnosis was verified by the pathologist, or where a characteristic pyelogram was supported by sufficient clinical evidence.

Of these 105 patients, 72 were submitted to a nephrectomy, 10 had an exploratory operation, 3 had biopsies, and in 20 cases no operation was done. End results are available in all but 6 cases. Of the patients who had nephrectomies (Table 1), 45

available in 1 case. All 20 unoperated patients died within fifteen months except 1, who lived for three years.

The histopathology of this series (Table 3) showed 7 Wilms's tumors in children, 5 adult sar-

are dead, 22 are living, and there are no follow-up reports in 5 cases. Of the 45 dead, 37 died within the first year, 3 within the second and third years, and 5 developed metastases after five years. Of the 22 living patients, 7 have gone beyond the five-year period, 10 have passed the fourth year, and 5 are living and well without demonstrable clinical recurrence after three years.

An exploratory operation was performed on 10 patients (Table 2), 4 of these died following the exploration, and 6 died at home within the first six months. Of the 3 patients on whom the diagnosis was made by biopsy, 2 died—1 three months after the biopsy and 1 six years after it (the latter case illustrates how slow-growing some adenocarcinomas and hypernephromas can be), no follow-up is

comas, 1 epidermoid and 7 papillary carcinomas of the renal pelvis, and 65 adenocarcinomas or hypernephromas. In the 20 unoperated cases no pathological report was available, as the diagnosis of renal tumor was made by pyelogram, and clinical signs and symptoms. All the children with a Wilms's tumor died within six months after the nephrectomy. Of the 5 adults with sarcoma, 4 died within the first year, and 1 lived two years and nine months and died in diabetic coma. This

Table 3. *End Results in Cases of Renal Cancer, Arranged According to Type of Tumor*

TYPE OF TUMOR	NO OF CASES	END RESULTS
Wilms's tumor (children)	7	All dead.
Sarcoma (adults)	5	All dead. 1 lived 2 yr 9 mo. and died of diabetes.
Epidermoid carcinoma of renal pelvis	1	Living over 5 yr. no clinical evidence of recurrence.
Papillary carcinoma of renal pelvis	-	Four living and well (6 yr 4 yr 6 mo 3 yr 3 mo and 1 yr 3 mo. respectively). Two died postoperatively—1 had no operation.
Adenocarcinoma or hypernephroma	65	Five are living and well over 5 yr. 5 lived over 5 yr. and died of metastases.
No report	20	
Total	105	

All but 1 had a nephrectomy—1 had a ureterectomy and segmental resection of bladder.

patient had no demonstrable recurrence. Four of the 7 patients with a papillary carcinoma of the renal pelvis are living—six years, four years and six months, three years and three months and fifteen months, respectively. The single patient with an epidermoid carcinoma of the renal pelvis

From the Urological Department of the Massachusetts General Hospital, Boston.

*Assistant urologist, Massachusetts General Hospital.

is living after five years, and recent x-ray examination of the chest and pelvis failed to reveal any metastatic process. Among the 65 patients with an adenocarcinoma or a hypernephroma, 10 lived more than five years, but 5 of these died later of metastases.

Of the entire series, regardless of the type of lesion, 12 patients lived more than five years, and only 7 are now alive and comparatively well. This high mortality was the incentive for further study as to end results.

Every available article listed in the *Index Medicus* and in the *Index Catalogue* of the Library of the Surgeon-General's Office has been reviewed. I pass over the early literature on the subject, including that of Israel, Garceau, Albarran and Imbert, Guillet, Richards, Héresco, Legueu, Denaclara, Chevalier, Hedrén and many others. These articles are very interesting but in a sense disappointing. The operative mortality at the time these men wrote was extremely high. With the increase in our knowledge of operative technic and methods, the operative mortality has definitely decreased. With this decrease one would expect to see a relative increase in the number of ultimate cures. This, however, has not occurred. Berg reported 25 patients with renal cancer, all of whom were dead in seven years. In Paschen's series of 268 collected cases, only 17 per cent were free from recurrence after three years. Pleschner reported 17 per cent cures at the end of three years and 5 per cent at the end of five years. In a series reported by Smith and Shoemaker there were only 7 cases out of 62 that lived over five years, 4 of these died later on from recurrence. Hyman in 42 postoperative cases reported only 9 per cent of five-year cures. Bull recently reported 37 cases of kidney tumor, of which only 5 are free from recurrence—three, thirteen, twelve, eight, and eight years, respectively.

Muir and Goldsmith had 16 per cent cures in 37 cases. Swan showed 20 per cent cures in 51 cases. In the 25 cases reported by Lazarus, there were no five-year cures, however, some patients in this series were operated on recently and may later prove to be cured. Rafin presented 20 cases, 4 of which (20 per cent) went beyond the five-year period. Kimball and Ferris showed that in their series of 74 cases of papillary carcinoma of the kidney there was recurrence in 75 per cent of those who had only a nephrectomy (40 cases), 68 per cent of those who had a nephrectomy and ureterectomy (25 cases), and only 25 per cent in those who had a nephrectomy, a ureterectomy and partial segmental resection of the bladder. Of the 8 cases of papillary carcinoma reported by Scholl, only 2 were free from recurrence, these patients had survived two and a half and four months, respectively. Mock

was able to report on 23 of 25 operative cases for papillary carcinoma of the renal pelvis. He traced 18 of these and found that only 5 patients remained well, but he did not state the postoperative duration. In the 45 cases of pelvic papillary tumors reported by Cabot and Allen, only 8 patients lived more than five years. Geschickter and Widenhorn report only 4 five-year cures in 84 cases of cortical tumor of the kidney (hypernephroma and adenocarcinoma), 3 of the 4 patients had metastases. MacKenzie in his series of 27 cases reports only 4 that he believes can be considered as cured, but many of the cases have been operated on recently, and there may well be more cures. Chute was able to report only 5 five-year cures in 43 cases. Wright in his 19 cases of hypernephroma had only 3 five-year cures. In 15 cases reported by Phillips there were no five-year cures. In the 57 cases of squamous-cell carcinoma of the renal pelvis reviewed recently by Gilbert and Macmillan there were no five-year cures. This tabulation of results could be carried on indefinitely to embrace such articles on the subject as those written by Roth and Schwoerer, Thomas and Regnier, Kretschmer, Scholl and Foulds, McCown, Stricker, Lindstrom, Ipsen, Michaelsson, Ljunggren, Hryntschak, Fedoroff, Key, Nevinny, Cutler, Deuticke, Warner, Carson, Dóza, Fischer, Demel, Grauhan, Heppner, Lubarsch, Nicolich, Sysak and Jurkewytch, and Swift-Joly. Suffice it to say that all the reports in the literature show the dreadful mortality of this disease.

I shall not go into the question of Wilms's tumor in children, for the mortality in this type of tumor is well known. The number of cures reported could easily be tabulated on one small page. We are led to believe that certain forms of renal cancer are more curable than others. We all know the terrific mortality of Wilms's tumors and the almost equal mortality of the sessile tumors of the renal pelvis, but we are in the dark as to the actual curability of papillary tumors of the renal pelvis, and especially the cortical tumors, such as hypernephroma and adenocarcinoma. I am sure that the number of cures in the cortical tumors would be further reduced if the reports as we find them in the literature had covered more than five years. There are innumerable reports of recurrence either in the operative scar or by metastasis in patients who have gone beyond the five-year period, particularly in cases with adenocarcinomas or hypernephromas.

Why this tremendous mortality? The answer, I believe, is not difficult. In the first place, inability to make an early pathological diagnosis is the *bête noir* of this disease. We may have been deceiving ourselves in believing that an early clinical diagnosis indicates an early pathological one. Noth

ing could be farther from the truth. An illustration of this point is the case of a male patient of thirty-eight who entered the hospital with a history of hematuria of three days' duration. He was otherwise perfectly well, and on entry had not an ache or a complaint. He was operated on and a moderate sized renal adenocarcinoma was removed. The patient was well for four years and

Figure 1. Small adenoma found at necropsy

then developed metastases to the brain and lungs. Although the clinical diagnosis was made early, the pathological process was fairly well advanced.

It is true that renal cancer is diagnosed much earlier now than it was before the introduction of the cystoscope, yet a casual glance through the present-day literature will soon convince any skeptic that the great majority of patients with renal cancer have a fair-sized growth when first seen or operated on. This does not mean that there is an exact relation between the size of the neoplasm and the ultimate prognosis, but it gives some indication of how long the process has gone on. It is fair to assume that the longer the duration of the neoplastic process, the greater the chance for venous and lymphatic extension. The small renal tumors that are found at necropsy, as illustrated in Figures 1 and 2, are almost never seen at operation or diagnosed clinically. The reasons are obvious. They rarely give clinical symptoms, and we have no means at our disposal to visualize them by x-ray. It would be the ideal procedure to make a diagnosis before these growths have produced their characteristic deformities of the excretory portion and contour of the kidney, as seen by x-ray. It is precisely at this stage that operative cure could probably be effected in most cases. I say "most cases," for in some instances the lesion may be small and yet the patient may have diffuse metastases. Fortunately this is the exception.

Another factor which prevents early diagnosis and indirectly increases the mortality is the insidious nature of the disease. The number of patients with renal cancers that fall into this group is not small, and they defy the acumen of the best

clinicians. They present no urinary signs or symptoms, but are diagnosed clinically when the disease affects other organs. I know of no cancer that can give as little warning as a renal cancer. Creevy in a very excellent paper has recently rediscovered and illustrated this point. These patients may have presenting symptoms such as cough, neurologic ailments or gastrointestinal disturbances. In 9 out of his 38 cases, Creevy found that the patients first sought his advice because of symptoms referable to the lungs, usually in the form of cough, pain in the chest or hemoptysis. We have had cases in our series that are illustrative of this point. One, a woman, fifty years of age, was seen by her doctor for cough of one year's duration. Physical examination revealed a large left kidney, and x-ray examination of her chest showed a metastatic nodule. There was no history of hemoptysis. It is extremely rare, however, to have hemoptysis due to a secondary metastatic nodule in the lung, whereas most of the primary bronchiogenic tumors do produce hemoptysis. This point is worthy of note. Creevy states

There is no doubt that a fairly high percentage of the cases of renal neoplasm will continue to escape recognition until late in their course, not merely because patients are prone to delay medical consultation, and because the disease often produces syndromes difficult to identify, but chiefly by reason of the fact that the first symptom to attract the patient's attention is so often due not to the tumor itself but to a metastasis or local extension. This was the case in 33 per cent of the cases in the clinical series, in 50 per cent of those in the autopsy series and in 41 per cent of those in the whole group—a disconcertingly high proportion.

Our series, too, is with other large series in the literature, includes cases in which the diagnosis

Figure 2. Small adenocarcinoma found at necropsy

was made after metastasis had taken place. A child of two and a half years complained of limping of the right leg of two weeks' duration. X-ray of the upper end of the femur showed a lesion, which was interpreted as being either an early tuberculosis, an early osteomyelitis or a beginning

primary tumor Abdominal examination revealed a fair-sized mass in the right upper quadrant, which at operation proved to be a Wilms's tumor of the kidney In one case, a man of sixty-seven developed an enlarged supraclavicular lymph node, which on biopsy proved to be metastatic hypernephroma In another, a woman of sixty-six, a diabetic, complained of "stomach trouble" for three and a half years Palpation of the abdomen revealed a huge right-upper-quadrant mass, which at operation proved to be a fibrosarcoma of the kidney In still another, a man of sixty-three entered with a chief complaint of constipation over a period of many months He had no urinary symptoms but his abdomen was markedly distended Physical examination revealed an enormous mass occupying the right upper quadrant, and x-ray examination showed metastases to the spine and lungs

The literature, both past and present, is replete with such case records Chukry cites the case of a man fifty years old who during defecation felt a sudden numbness of the arms and legs and had a definite left hemiplegia He had no symptoms referable to the genitourinary tract. At autopsy a renal cancer was found with extensive metastases to the brain, lung, mediastinal glands and myocardium Johnson cites the case of a Negress, sixty years of age, who had a spastic paralysis of both legs of four days' duration and a microscopic hematuria Physical examination revealed a huge mass in the right lower quadrant—kidney cancer Radimska-Jandova and also Barjon and Japiot add similar cases with neurological symptoms Wodsack included in his 54 cases a number of patients with extensive metastases, but without any urinary symptoms Metastatic skin nodules (Cochez and Busser, Lubarsch), extreme anemia (de Luna), cough (Harvier and Lemaire), pleurodynia (Shuman) and hoarseness (Turner, Memzel) may be the first symptoms of renal cancer Simpson cites an interesting case of a boy who was unable to move his leg owing to partial collapse of the first and second lumbar vertebrae A small renal tumor was removed which on microscopic examination proved to be a spindle-cell sarcoma The boy died a few weeks later In his comment Simpson stated "Such a lamentable result after removal of a tumor, only four days after the first symptom, makes one wonder whether we are justified in telling the public that the cure of cancer is only a question of early diagnosis" I believe that we are justified in so doing provided we keep forever in mind that we seek an early pathological diagnosis and not an early clinical diagnosis

The third factor that indirectly increases the mortality rate is that we have very few, if any,

early symptoms This is of course true of practically all types of deep cancer Braasch once pointed out that hypernephromas usually grow slowly, and in their early stages cause few if any, clinical symptoms The classic triad of hematuria, tumor and pain which are described in every textbook on renal cancer means very little so far as early diagnosis is concerned

According to Neff, "a patient is lucky whose kidney tumor causes bleeding in the early growth." Hematuria is the one symptom which is so often stressed in the literature Both the laity and the physician have been told time and again of the necessity for investigation when urinary bleeding is present. In fact, it has not been uncommon in the past to accuse physicians in small communities of not investigating a hematuria and thus making more nearly possible an early diagnosis I am strongly in favor of investigating every case of bloody urine, but I am not so sure that this will increase the chances of successful diagnosis of early pathologic lesions, especially of cortical tumors We must remember that in order to have hematuria from a cortical tumor the lesion must extend into the renal pelvis or its appendages, or, as shown by Patch and Rhea, produce bleeding by congestion of the subepithelial spaces In our series the urinary sediment was negative in a fair percentage of cases By this is meant that no erythrocytes could be found in the urines of these patients when they entered the hospital This does not necessarily signify that they had not had hematuria at some other time, but simply that when they were first seen no red cells were found in their urines, nor did they give a history of hematuria

Gross hematuria was present in only a small group of cases This is very significant It may be that in this particular series the incidence of hematuria was low, but in the literature, report after report can be found where a fair percentage of the cases did not have macroscopic bleeding In view of this last statement, how can anyone make an early diagnosis in these cases? The fact is that we do not make it, in a number of our cases the growth was of fair size and the patient had only recently complained of hematuria Quite a number presented hematuria as the initial symptom, yet on physical examination a large tumor mass was present Nearly all these cases were in the parenchymatous group

This shows strikingly that the symptom—mass or tumor—was not sufficient in itself to bring the patient to the doctor, but that the addition of hematuria was Hematuria, although a fortuitous sign, as stated by Neff, does not necessarily mean an early tumor even though it is a presenting symptom and of quite recent date The patient who had one of the largest tumors in this series had his first hematuria three days before death

In Wilms's tumors in children, hematuria is not a very early symptom. Prather and Crabtree found it in only 15 per cent in their group of 111 cases. In Mixer's series of 41 cases and in Schippers's cases, hematuria was present in 2 per cent and 10 per cent, respectively.

The value of tumor as a sign in the early diagnosis of kidney cancer is likewise small. Patients as a rule do not continually examine their abdomens for tumor, and the chances are that when a mass is palpated the lesion has gone on for a considerable time. The growth has probably extended beyond the capsule or into the venous system. There are obviously exceptions to this rule, but in the main it must be conceded that the very finding of a tumor mass militates against an early lesion. It may be an early diagnosis so far as the physician is concerned, but it is not an early pathologic process. This is well illustrated in the Wilms's tumors found in children. We all know that the chief complaint in this type of tumor is an increasing swelling of the abdomen due to a large mass. We know also the dreadful prognosis in these cases. The number of reported cures in the past thirty years can be counted on two hands and the total number is probably not greater than twice those reported. This is an appalling fact.

Pain as an early symptom I believe to be of extremely doubtful value. It is the chief complaint in most cases of epithelioma of the renal pelvis. As it is a subjective symptom, it depends entirely on the individual's threshold for pain. Persons with a slight degree of pain usually carry on for a long time before they consult a doctor. Invariably they hope that the pain will pass off, and attribute it to some other cause. Fortunately most pain does pass off and no cancer develops, but only when the pain is severe or hinders his daily work will the patient consult a physician. Imagine every woman's going to a physician because her back hurts! I am not sure that the average physician would welcome such a practice. The symptom itself is so indefinite that it is of value in the diagnosis of renal cancer only when associated with hematuria. Of course, many times pain is due to a large tumor.

The fourth factor that tends to increase the ultimate morbidity is failure to do a radical operation when circumstances permit. A radical disease such as this requires radical treatment. Just how much this would increase the percentage of operative cures above the 10 to 25 per cent recorded in the literature is doubtful. It might, however, reduce the number of postoperative recurrences. The term "radical" is of necessity all-inclusive. There are some procedures that can be easily accomplished, and others that are not so easy.

Removal of all the perirenal fat can and should always be done. A large percentage of parenchymatous tumors when operated upon already extend beyond the true anatomic capsule into the perirenal fat. Statistics on this point are hazy, but this percentage may well be far greater than we suppose. In this series, extension beyond the renal capsule was present in a large percentage of cases.

The advisability of doing a nephroureterectomy, with or without a segmental resection of the bladder, in papillary tumors of the renal pelvis is unquestionable, but it is not always feasible, nor is it advocated by all urologists. Nicolich feels that in most cases of tumor of the renal pelvis, whether of benign or malignant histologic structure, a nephroureterectomy should be done. However, since this radical procedure increases the operative risk, it should be done only when the general condition of the patient allows it. In old and weak patients one should do a simple nephrectomy, as a permanent cure is often possible. The nephroureterectomy may be done in one stage or in two (Smith and Gilbert).

It is true that not all cases of papillary tumor of the renal pelvis give transplants to the ureter and bladder, but it is equally true that no one can say offhand which papillary tumor will give rise to transplants and which will not. It is striking to see the percentage of recurrences of this tumor and the number of deaths definitely attributed to it, notwithstanding that clinically it is usually diagnosed early and that pathologically the growth is usually of low malignancy. Stricker in 175 cases of papillomatous tumor of the renal pelvis found transplants to the ureter and bladder in 47 per cent. In the cases where nephrectomy alone was done, 35 per cent had recurrence in the bladder or ureter. Kimball and Ferris reported 74 cases found in the literature, in 50 of which the tumors recurred in the ureter and bladder following nephrectomy. In 24 cases of their series, the ureter or bladder was affected at the time of examination or operation. Cabot and Allen report 33 cases of papillary tumor, in 20 cases (44 per cent) it was localized to the pelvis, and in 13 cases (29 per cent) the ureter and bladder had implants.

The benignity of the tumor is not necessarily a guarantee of cure (Smith and Gilbert), for not infrequently malignant metastases from such tumors have been found. The transplants may become evident at an early or late period following nephrectomy, this naturally necessitates keeping the patient under strict surveillance. Asch removed a small papilloma of the renal pelvis which was followed in two months by a secondary deposit in the bladder about 7 cm. in diameter. The blad-

der was resected and six weeks later the patient died. Extension to the scar was found. Zuckerlandl reports a case where six months following nephrectomy twenty tumors from 1 to 2 cm in diameter were found in the bladder. The bladder was negative at the first examination. Nitch had to do a total cystectomy owing to extensive papillomatosis of the bladder and ureter following removal of a papillary tumor of the renal pelvis. Necker cites a case in which subsequent to a nephrectomy the bladder became filled with papillomatous masses, whereas six months before it had been free of growth.

Two cases in our series are typical examples. One was that of a man of fifty-one who entered complaining of hematuria of eighteen months' duration, a diagnosis of papillary tumor of the renal pelvis was made. A nephroureterectomy was decided upon, but only a nephrectomy and partial ureterectomy was done, owing to the patient's condition on the operating table. He had an uneventful convalescence. A ureterogram and cystoscopy at the time of operation were negative. Fourteen months later the patient returned with a small tumor at the ureterovesical orifice. A complete ureterectomy and segmental resection was done, and up to the present time (five years) there are no demonstrable vesical recurrences. In the second case transplants appeared promptly. A nephrectomy was done for papillary carcinoma of the renal pelvis, and at the same operation part of the ureter was removed. At operation a cystoscopy and a ureterogram were negative. Four months postoperatively cystoscopy revealed a large tumor mass obstructing the ureteral orifice on the same side as the tumor. A ureterectomy and partial segmental resection of the bladder were done, the ureter was filled with small papillary implants. These two cases can be duplicated in any large series in the literature. They simply go to prove that it is impossible to tell before operation, even with a negative ureterogram and nothing at cystoscopy, whether very small transplants are present in the ureter or will be present in the bladder at a later date.

Other radical procedures, such as removal of solitary metastases when found in bone and deliberate opening of the vena cava to remove tumor plugs, have been advocated. The number of patients who fall into these two groups is indeed small, hence radical procedure of this sort would do little to raise the number of cures. Berg in 1913 called attention to the fact that "the metastases of hypernephroma are very often single," and added that "whereas with other varieties of malignant tumor one would decline to remove either the primary or secondary tumor because the metastatic

foci of disease are apt to be multiple, yet in this variety of growth we would be justified in extirpating both the primary tumor and the secondary deposit."

It is not a simple problem to say when a metastatic nodule is a solitary one and when it is not, but I believe one is justified in assuming that it is if a thorough x-ray examination of the rest of the bony skeleton and lungs is negative. Some of these cases of course have metastases in deep viscera not visualized by x-ray. That single osseous metastases do occur is proved by autopsy material. Lehmann collected in the literature 56 cases of bony metastasis from carcinoma of the kidney and found that in 13 of them the lesion was a solitary one. Five of these 13 were proved by necropsy, and in 8 the clinical examination revealed no secondary deposits. Hartmann cited a case of a man with a renal neoplasm and metastases to the humerus. The patient refused operation and later died. At necropsy no other metastatic nodule was found. Schinz and Uehlinger report solitary osseous metastases in 6 of their 34 cases. Smith and Shoemaker add the case of a male patient on whom a shoulder-girdle amputation was done, who had only a solitary lesion in the humerus. He refused a nephrectomy and died five years later. At the time of operation the lesion in the humerus was the only skeletal one present. Albrecht cites a case in which amputation was done for a supposed osteosarcoma, it proved to be a metastatic hypernephroma. The patient lived for five years, and at necropsy no other metastases were found. Many other cases of solitary bone metastases may be mentioned (Tixier, Bland-Sutton, Colmers, Geschickter, Broster, McKechnie, Bull, Pleschner), but considering the total number of reported cases of kidney cancer, they constitute a very small percentage of the whole.

Recently at this hospital, Dr. Churchill removed a pulmonary metastasis arising from a carcinoma of the kidney. So far as known, this is the first case of a successful lobectomy for such a purpose. The patient, a woman of about fifty, consulted a physician because of a persistent cough. X-ray of the chest revealed a metastatic nodule about 4 cm in diameter. Abdominal palpation showed the presence of a tumor mass in the right upper quadrant. X-ray photographs of every bone in the body revealed no bony metastases. I helped Dr. Barney remove the kidney. At operation there was no evidence of extension to the renal vein or vena cava. The perirenal tissue was not invaded by the neoplasm. Following the operation the chest was irradiated, without effect. Another series of deep roentgen treatments of the chest did little to decrease the size of the metastatic focus. Six months

after nephrectomy Dr Churchill did a lobectomy, four years have passed since then, and the patient is now in good health and to the best of our knowledge free of metastases. This case is cited as an incentive to others to remove solitary metastases.

Whether one should open the vena cava and remove the tumor plugs we cannot state, owing to lack of experience. In not a single case in this series was this done. That it is technically possible has been proved beyond question (Mayo), but whether the procedure decreases morbidity to a marked extent is doubtful. It is a fact that there are recorded in the literature many cases in which at nephrectomy tumor plugs filled the renal vein and vena cava, and yet the patients lived for years. Ljunggren cites a nephrectomy case in which at operation tumor tissue was noted in the renal vein and vena cava. Ljunggren examined the thrombus in that portion of the renal vein removed with the tumor and found that it consisted of hypernephromatous tissue. The patient lived for ten years and then died of metastases.

Allemann and Bayer, Judd and Hand, and Smith and Shoemaker record similar instances. The case cited by Smith and Shoemaker is interesting. The patient had a nephrectomy done for hypernephroma in 1913. At operation extensions to the spermatic and renal veins were noted. The patient lived for ten years and died of "cardio-renal disease." It has often been shown at necropsy that although the renal vein and vena cava were occluded with tumor, no signs of metastasis could be found (Rehn). This is a valid argument in favor of deliberate opening of the vena cava in some cases, but one should not forget that it may be extremely difficult to ascertain at operation just how much tumor thrombosis of the vena cava exists. The tumor plugs may extend to the right auricle (Quinland, Pleasants, Crowdy, Fraser, Jacobson and Goodpasture, Israel, Hinman, Albarán and Imbert, Osler, Lebert, Coyne and Troisier, Polayes and Taft, Carson, Oberndorfer and Rubbert, MacCallum, Taylor, Foster and Gerhard, Gayet and Bérinel), or down to the bifurcation of the iliacs (Crowdy, Jacobson and Goodpasture). This most radical procedure necessitates a transperitoneal approach, one which is advocated by all competent urologists for parenchymatous tumors of the kidney and which allows a greater exposure of the operative field than is possible with a conservative operation. There are, however, many renal tumors that can be easily removed by the usual retroperitoneal approach.

The value of deep x-ray therapy in the treatment of renal cancer is at present doubtful. From the maze of literature on the subject a few facts have been brought to light. They should be kept constantly in mind in applying this form of therapy to

such pathologic processes. So far as I am aware, no patient with a renal neoplasm, regardless of the histopathology, has been cured with deep roentgen-ray treatment alone. This has been enunciated by Mintz, Wharton, Harrah, Portmann, Dean and Pack, Priestley and Broders, Waters, Pohle and Ritchie, Prather and Crabtree and Schippers et al. In the 12 cases of Wilms's tumor reported by Priestley and Broders and in the 3 cases (malignant cystadenomas) reported by Geschickter and Widenhorn, in which irradiation alone was used, all the patients died. Perhaps when the roentgenologist is able to deliver a dose to the tumor at a greater depth without too much harm to the neighboring structures and too great a systemic effect, or, as Dean and Pack imply, when there is better equipment, a new era in its application will open. Until then no curative effect should be expected from irradiation alone. Preoperative irradiation of renal cancer has recently been extolled by many prominent urologists and roentgenologists. Its chief purpose is to shrink any large new growth, mainly Wilms's tumors and adenocarcinomas, so that an inoperable neoplasm can be made operable and be entirely removed. It has been demonstrated that after preoperative irradiation the extirpated tumors show, microscopically, strands and nests of vital tumor cells surrounded by areas of fibrosis of more or less density (Randall, Wharton, Dean and Pack). Necrosis of the tumor, varying with the amount of irradiation, takes place.

Wharton feels that failure to cure malignant tumors of the kidney is due to inability to remove completely the local growth. This inability he ascribes to a number of conditions: the pronounced size of the tumor, the thinness of the capsule, the extreme vascularity and friability of the mass, invasion of the perirenal structures and the extension into the renal vein. "The one factor," he continues, "which has been responsible for more operative deaths than all the others combined, the size of the tumor, has remained beyond control until the present time." There is no question that deep roentgen-ray treatment decreases the size of a renal neoplasm. It is extremely efficacious in Wilms's tumors, moderately so in adenocarcinomas and hypernephromas, and almost nil in tumors arising from the renal pelvis. As Wharton states, "the effect that preoperative irradiation has on the chance of ultimate cure cannot be reported, as this can only be determined with the passing years." Since Wharton's article, enough cases having preoperative irradiation for Wilms's tumor have been reported to give the clinicians some idea of what may be expected. It has not so far been successful as a curative agent when used in conjunction with late operative removal.

of the tumor, but the fact that it is still in its infancy is no bar to its continuance

Postoperative irradiation of the local area after nephrectomy is of questionable value. It is usually carried out in all clinics in cases where the tumor mass has not been completely removed, and in some clinics as a routine measure. All authors are not in accord as to whether postoperative irradiation should be given where a thorough removal of both the growth and the fatty contents of the renal fossa has been effected. Exactly how helpful it is as a curative or retardive measure in any single case is hard to judge. Whether some operated cases have been cured by this adjunct is extremely difficult to ascertain. I believe this form of therapy to be of very little value in cases where a thorough job of removal has been done. Delayed postoperative irradiation is usually confined to cases where recurrence has taken place in the kidney bed, in the scar or at distant points. Once there has been recurrence in the renal fossa, regardless of the pathological type of tumor, little can be expected from irradiation except a slight decrease in the size of the mass. It often happens that the recurrence is less radiosensitive than the original tumor, so that subsequent irradiation is not beneficial. A recurrence of a tumor nodule frequently takes place in the old nephrectomy scar, even years after the nephrectomy. Tikhoff cites an elapsed period of ten years, Bland-Sutton, eleven, Smith, seven, Graves and Mabrey, twenty, Bull, seventeen, Quinby, nine, Michaelsson, ten, and Muir and Goldsmith, fifteen. Irradiation here may be of some aid, but most urologists hold that the secondary deposit should, if possible, be removed surgically. Interstitial irradiation is sometimes useful for this type of recurrence provided the metastatic nodule is small.

It may not be amiss at the present time to state that our ideas about the value of x-ray therapy as an adjunct in the cure of renal cancer may change overnight, so to speak, with the newer developments in technic, dosage and high-voltage treatment.

From the maze of statistics of which this communication is a very minor part, I have formed a definite opinion as to why the percentage of five-year cures in this disease is so small. Although failure to do radical surgery in suitable cases is an element in reducing the number of late cures, the very nature of the disease is by far the largest single factor making for a high mortality. It is obvious that we see proportionately few cases of early pathologic lesions. We may see them early clinically, but pathologically they have probably either invaded the venous system or extended be-

yond the confines of the renal parenchyma. Unquestionably the end results would be much better in patients with renal cancer if they were treated soon after their first hematuria. Only persistent education of the laity as to the significance of urinary bleeding will add to the longevity in this group. But how about those who have had no hematuria, and whose first sign of renal cancer is to be found outside the urinary tract? This group is not by any means small, and its members are the victims of the well-known insidiousness of renal cancer. Their situation is analogous to that of patients with cancer in other deeply situated organs. The results will be greatly improved when the diagnosis can be made in this asymptomatic period while the growth is still limited to the kidney. Until that time we should not expect the impossible.

DOCTORS AND BOOKS

PAUL D. WHITE, M.D. *

BOSTON

IT IS an honor to be asked to address you on the occasion of the inauguration of the Gerrish Memorial Library and Lectureship. We live in a land and in a time of opportunities that we appreciate all too little. I would begin, therefore, with a note of gratitude and a hope that we may deserve and cherish the privileges accorded to the medical profession in our country.

To speak of the value of a medical library is trite indeed, for everyone is aware of it. Many are familiar with Osler's saying in 1901 that "to study the phenomena of disease without books is to sail an uncharted sea." Oliver Wendell Holmes in his dedicatory address at the opening of the Boston Medical Library in 1878 said "A physician of common sense without erudition is better than a learned one without common sense, but the thorough master of his profession must have learning added to his natural gifts." And Harvey Cushing in 1926 wrote "As the calorimeter tells the activity of the patient's metabolism, so may you determine the plus or minus activity of the local profession in any district by the condition of its library." But there are still other things about doctors and books that are, I believe, worth saying. It is of some of these that I shall speak.

The first half of my address will be concerned with the importance of the record of ideas and facts, with the unimportance of priority and with the interesting subject of rediscovery.

Those who read medical books or journals often appreciate that what they read is what has been in their own thoughts in whole or in part for a long time, as the result of reflection, experience or research. They may react with pleasure that others agree with them, or with envy that they themselves had not had the time or inclination or industry to do the writing first, or with annoyance because of what they believe to be errors or omissions. Actually it is vain and idle to boast or to quarrel about priority. Always men have lived in periods where others besides themselves have been at work on the same problem, no matter how unusual or bizarre. I myself remember being surprised some years ago, when I was dissecting a whale's heart, on being told that someone in Norway was doing the same thing at that very time.

The larger and more important the problem, the greater as a rule is the number of solutions of that problem. Many contributions have been made toward its solution by many different individuals, sometimes the same discoveries being made simultaneously and entirely independently by different workers. Then, when the pieces of the puzzle are almost assembled, some inspiration or clue may suddenly complete the picture, and the lucky person may receive more than his due of credit. After all, it may be that the first step in the analysis of the problem, often in history, was more vital than the last. No contributor deserves credit, and the more we know of medical history the more we find this to be true, new or forgotten names take rank with those that have long been well known—for example, the Flemish artist van Calcar, pupil of Titian, who drew the splendid anatomical pictures for Vesalius. Even the great Harvey but for the masterpiece of the discovery of the circulation of the blood which had long been building up himself studied in northern Italy under anatomists who had learned from their forerunners and their own observations that there was a pump sending blood from the right ventricle through the lungs to the left ventricle, receiving thereby a vital spirit which the left ventricle pumped on to the tissues of the body, that the blood in the veins carried nutriment back to the heart, that there were doubtless capillaries—too small to see—connecting arteries with veins, and that the veins contained valves. Harvey noted that the valves in the veins were so constructed that they prevented (not simply retarded) the retrograde flow of blood through the veins. This was the clue that he seized upon, by simple, clear experiments he demonstrated that the blood flows from left to right ventricle through the systemic arteries and veins to complete the circulation already in part understood in the pulmonary circulation. But even he could not complete the picture. He too assumed that there must be capillaries, but it remained for Malpighi several decades later to discover them.

I have presented this instance because Harvey's discovery is generally regarded as the highest landmark in the development of our knowledge of medical science. Yet it is clear that great as was his work, it was but one contribution among many in the same field, had not Harvey made the

The Gerrish Memorial Lecture, read at the Central Maine General Hospital, Lewiston, Maine, May 26, 1937.

Physician, Massachusetts General Hospital. Lecturer on medicine, Harvard Medical School.

covery, it is well nigh certain that someone else would have made it within a relatively few years, for the time was ripe. Roesler, formerly of Vienna and now of Philadelphia, has recently most aptly quoted Sir Michael Foster

To whom shall be given the honor of a discovery. This question can never be answered fully, science is a continuous process, each investigator must of necessity build on the work of those who come before him. What we know and what we think is a stream which flows by us and through us, fed by the far-off rivulets of long ago.

Harvey himself in 1628, in Chapter I of the *De Motu Cordis*, in speaking of this very subject quoted the old man in the comedy *Adelphi* by Terence

For never yet hath anyone attained
To such perfection, but that time, and place,
And use, have brought addition to his knowledge
Or made correction, or admonished him,
That he was ignorant of much which he
Had thought he knew, or led him to reject
What he had once esteemed of highest price.

Incidentally it is of interest that the priority of the announcement of knowledge of the pulmonary circulation in the century before Harvey is still in doubt, an academic point and yet one historically intriguing. Realdus Columbus, professor of anatomy in Northern Italy, published his *De Re Anatomica* in 1559, and in that volume is the description of the pulmonary circulation. Six years earlier, however, the circulation of blood through the lungs was referred to incidentally in the religious tract *Restitutio Christianismi* by Servetus, who was that same year burned at the stake for his religious views. And much earlier still, in the thirteenth century, the theory of pulmonary circulation was advanced quite clearly by Ibn-an-Nafis (Haddad and Khairallah*). It may be that still earlier mention was made in manuscripts now lost. It was a time, of course, when verbal instruction and knowledge was the rule because of the expense and difficulty of writing and of printing. It is probable that Columbus and others had taught the pulmonary circulation for years before the appearance of *De Re Anatomica*. As it stands now, however, Ibn-an-Nafis holds the priority of announcement.

One other example I would cite in emphasizing this point, an example nearer home and in our own times. In 1914 Dr. Richard C. Cabot wrote an important paper on the causes of heart disease, a landmark in the study of diseases of the circulation. It was simple and clear, as are most significant contributions in medical science. He did not think it was a masterpiece or that he was the only man in the world with such thoughts, but he recognized that many workers and writers in medicine were not aware of the importance of

these findings. And so he wrote them down. A few days ago one of Cabot's contemporaries told me that what he wrote in 1914 was common knowledge at the time, and implied that little credit should be given to the contribution. It is true that others had the same ideas, but they did not realize that thoughts in order to live, or even to travel far from their immediate neighborhood, must be recorded.

That is the first important message of my talk to you today. It is, in sum, that if a doctor has learned something from his experience in practice or in research that is not clearly or widely known, and is not recorded in print at all or as he believes it should be, it is his duty to write briefly and clearly his findings. Such a duty may become a pleasure, but it goes without saying that the doctor must make sure, first, of the truth of his conclusions, secondly, of their importance, and thirdly, that they are not already on record. Thus any of us may be writers of books or articles as well as readers of books, if we keep our eyes open, and have enough curiosity and opportunities, judgment and persistence. We certainly have more than enough so-called medical literature now, but there is still plenty of room for worth-while books and articles.

The next message I would give you naturally evolves from the first. Do not fill your library full of modern books and journals; leave plenty of space and money for the more important books of the past, dating back if possible to the time of the first printing presses. It is not essential that you shall have any priceless incunabula, that is, books printed before 1500, but it is important that you secure some representative volumes of the sixteenth, seventeenth, eighteenth and nineteenth centuries, even though a considerable proportion of them will be in Latin, German, French or Italian. There is always someone in every community who can help you in the translation of these languages when you are looking up some special points of interest. A classic or a leading textbook of the past is far more valuable than a second-rate volume of the present, in a practical sense as well as from the standpoint of the book-collector. Although many important medical books and articles are being published today, much of the enormous mass of writing is not worth the paper it is written on. Only a small percentage of books and journals is necessary to have close at hand for ready reference, it is always possible to go or to send to Washington or New York or Boston or elsewhere for the rarer or less important works. The committee that will have the selection of your books must be very wise, its judgment will be more important than the size of the budget for the purchase of books.

*Haddad, S. I. and Khairallah, A. A. Forgotten chapter in history of circulation of blood. *Ann. Surg.* 1941, 153: 1024.

DOCTORS AND BOOKS

PAUL D WHITE, M.D.*

BOSTON

IT IS an honor to be asked to address you on the occasion of the inauguration of the Gerrish Memorial Library and Lectureship. We live in a land and in a time of opportunities that we appreciate all too little. I would begin, therefore, with a note of gratitude and a hope that we may deserve and cherish the privileges accorded to the medical profession in our country.

To speak of the value of a medical library is trite indeed, for everyone is aware of it. Many are familiar with Osler's saying in 1901 that "to study the phenomena of disease without books is to sail an uncharted sea." Oliver Wendell Holmes in his dedicatory address at the opening of the Boston Medical Library in 1878 said "A physician of common sense without erudition is better than a learned one without common sense, but the thorough master of his profession must have learning added to his natural gifts." And Harvey Cushing in 1926 wrote "As the calorimeter tells the activity of the patient's metabolism, so may you determine the plus or minus activity of the local profession in any district by the condition of its library." But there are still other things about doctors and books that are, I believe, worth saying. It is of some of these that I shall speak.

The first half of my address will be concerned with the importance of the record of ideas and facts, with the unimportance of priority and with the interesting subject of rediscovery.

Those who read medical books or journals often appreciate that what they read is what has been in their own thoughts in whole or in part for a long time, as the result of reflection, experience or research. They may react with pleasure that others agree with them, or with envy that they themselves had not had the time or inclination or industry to do the writing first, or with annoyance because of what they believe to be errors or omissions. Actually it is vain and idle to boast or to quarrel about priority. Always men have lived in periods where others besides themselves have been at work on the same problem, no matter how unusual or bizarre. I myself remember being surprised some years ago, when I was dissecting a whale's heart, on being told that someone in Norway was doing the same thing at that very time.

The larger and more important the problem, the greater as a rule is the number of students of that problem. Many contributions may be made toward its solution by many different individuals, sometimes the same discoveries may be made simultaneously and entirely independently by different workers. Then, when the pieces of the puzzle are almost assembled, some inspiration or clue may suddenly complete the picture, and the lucky person may receive more than his due of credit. After all, it may be that the first step in the analysis of the problem, often lost in history, was more vital than the last. Every contributor deserves credit, and the more we learn of medical history the more we find this to be true, new or forgotten names take rank with those that have long been well known—for example, the Flemish artist van Calcar, pupil of Titian, who drew the splendid anatomical pictures for Vesalius. Even the great Harvey but finished the masterpiece of the discovery of the circulation of the blood which had long been building, he himself studied in northern Italy under the anatomists who had learned from their forerunners and their own observations that the heart was a pump sending blood from the right ventricle through the lungs to the left ventricle, receiving thereby a vital spirit which the left ventricle passed on to the tissues of the body, that the blood in the veins carried nutriment back to the heart, that there were doubtless capillaries—too small to see—connecting arteries with veins, and that the veins contained valves. Harvey noted that the valves in the veins were so constructed that they prevented (not simply retarded) the retrograde flow of blood through the veins. This was the clue that he seized upon, by simple, clear experiments he demonstrated that the blood must flow from left to right ventricle through the systemic arteries and veins to complete the circuit already in part understood in the pulmonary circulation. But even he could not complete the picture. He too assumed that there must be capillaries, but it remained for Malpighi several decades later to discover them.

I have presented this instance because Harvey's discovery is generally regarded as the highest landmark in the development of our knowledge of medical science. Yet it is clear that great as was his work, it was but one contribution among many in the same field, had not Harvey made the dis-

The Gerrish Memorial Lecture read at the Central Maine General Hospital, Lewiston, Maine, May 26, 1937.

Physician, Massachusetts General Hospital; Lecturer on medicine, Harvard Medical School.

in such exaggerated measure that their pupils, who were our own teachers, discovered their error and then swung too far in the opposite direction.

Anyone who finds it difficult to think of new problems to puzzle over need only review some of those mentioned in former days and then forgotten. Indeed, if he goes back in the literature two or three generations he may come across some clever notion or suggestion to follow up on, if he is unprincipled enough, to assume as his own. The great Corvisart, physician to Napoleon, in the preface to his translation of Auenbrugger in 1808 said that for all the current medical world knew of Auenbrugger's important discovery of the use of percussion in clinical diagnosis forty-seven years earlier, he (Corvisart) could easily have announced it as his own.

Oliver Wendell Holmes, in his address in 1878, referred to the need of a collection of the works of the old masters for every medical library. "Men were not all cowards before Agamemnon," he remarked, "or all fools before the days of Virchow and Billroth." He added

It does please me to read the first descriptions of parts to which the names of their discoverers or those who have first described them have become so joined that not even modern science can part them to listen to the talk of my old volume as Willis describes his circle and Fallopius his aqueduct. We need in this country not only the scholar but the *virtuoso* who hoards the treasures which he loves.

To hammer this thought home I conclude this first part of my address with two brief quotations from Osler's 1901 address at the dedication of the new building of the Boston Medical Library.

There is a third class of men in the profession to whom books are dearer than to teachers or practitioners—a small, a silent band, but in reality the leaven of the whole lump. The profane call them bibliomaniacs.

I should like to see in each library a select company of the Immortals set apart for special adoration.

Finally, as Lowell remarks,

'Tis man's worst deed
To let the things that have been run to waste
And in the unmeaning Present sink the Past.

* * *

The latter part of my address has to do with a subject of equal interest to that covered by the first. It concerns medicine as literature and literature as medicine.

It is indeed a pity that this golden age of medicine does not coincide with the golden age of literature. Many important facts and ideas are buried, or at least in part concealed, by verbose or clumsy or otherwise inferior writing. In this matter the early education and environment of the doctor are often at fault. Not only has much of the fundamental cultural training of the youth been neglected, but even the rudiments of penmanship,

spelling, grammar and literary style are often too hastily covered to establish good habits in the student of the present generation. It has become almost a commonplace that the average doctor writes illegibly, spells atrociously, constructs barbaric sentences and paragraphs and has an uncouth literary style. Since it is impossible to tell in childhood who will be the writers of medicine in the next generation, it would be wise to require of applicants for admission to the medical schools in the future a truly classical as well as a scientific fundamental education. The inclusion of Greek and Latin in language and literature, French and German, English in all its aspects, and history and archaeology in the pre-medical curriculum might easily make the difference between enjoyment and profit on the one hand and disappointment and neglect on the other, both in the reading and in the writing of important medical scientific papers and treatises. More and more we shall realize the truth of this, and shall strive to emerge from the barbarism of the medical literature of today to a higher level.

As I have already indicated, this situation has a practical as well as an esthetic bearing upon medicine. What is well written is much more likely to be read and believed than what is clumsily or dryly written. Many untruths and exaggerations in medical or other sciences have been so attractively presented in writing that they have been widely read and have vied with pure fiction among the best-sellers, while many facts and theories of the greatest importance are still buried in verbose, dull or unintelligible language in book or journal. Now and then there shines forth an exception in which a valuable discovery or thought is couched in such excellent style that it attracts early and lasting attention. These gems in books or reprints you should zealously seek and jealously save, no matter how ancient or modern, how long or brief, or in what language.

A few of the literary treasures in medicine are the *De Medicina* of Celsus of Rome—a finer piece of concise writing than the books of Galen which followed, the medical translations of Linacre, the *De Motu Cordis* of William Harvey, a clear, forceful and entertaining treatise as well as the announcement of a great discovery, the *De Aneurysmatibus* of Lancisi, physician of that very intelligent pope, Clement XI, one hundred years later, the *Opera* of Sydenham of 1666, the volumes on heart disease by Senac and Corvisart, physicians of the French Court in 1749 and 1806 respectively, the *De Sedibus et Causis Morborum* of Morgagni in 1761, the writings of Heberden and Withering at the end of the eighteenth century, the notable treasure on the heart by James Hope of London in 1832, Trousseau's *Lectures* of 1861,

We must be constantly on the watch for the announcements and descriptions of new discoveries and advances in the active medical progress of today, but we must also have a thought for the rediscoveries. The rediscovery of a fact or truth or the restatement of an important theory or teaching is almost as significant as its original presentation, but it is much more satisfying and less humiliating for the rediscoverer to know by careful historical research that he is a rediscoverer than for him to assume at the start that he is the originator. Medical history is full of rediscoveries. It may interest you if I cite but a few that have come in my own particular field, namely that of cardiovascular disease.

Lancisi, physician to Pope Clement XI at the beginning of the eighteenth century, described the engorgement and pulsation of the jugular veins that accompany enlargement and failure of the right ventricle, in fact, this phenomenon was for many years known as Lancisi's sign. It appears to have then been forgotten, two hundred years later it was rediscovered by James Mackenzie and his pupils, who apparently knew little or nothing of Lancisi's observations.

In 1832 Hope in England described clearly the congestion of the blood vessels of the lungs, along with the consequent dyspnea that results from failure of the left ventricle. This vital phenomenon was later almost completely neglected in English medical writings, and was even denied by Mackenzie and his school. It has now been rediscovered by writers of the English language, although one conversant with and sympathetic to French and German medical writings, at least in the last generation, would not have fallen into this error.

In 1715 Vieussens of Montpellier described the pulmonary stasis that results from the mechanical effect of mitral stenosis. Yet even in our own day there are many who fail to recognize this, and who do not realize that the dyspnea in uncomplicated marked mitral stenosis, whether in paroxysmal form with or without cardiac asthma, or in chronic form as the result of effort, excitement or infection, is not due to failure of either the left ventricle or the right, but to the overloading of the already congested pulmonary blood vessels by the increased rate of the over-strong right ventricle.

In 1749 Senac, physician to the French Court, wrote that he had often found quinine helpful in cases of rebellious palpitation. In 1914 Wenckebach reported that a patient of his had rediscovered this interesting fact. Now, in the form of quinine, cinchona bark is frequently used in patients

with paroxysmal tachycardia, auricular fibrillation and premature beats.

In 1785 Withering wrote that powdered digitalis leaves should be administered at the outset in the dose of from one to three grains twice a day, bearing in mind that thirty grains may be taken before nausea begins. In our own generation we rediscovered this optimal dosage. We knew, of course, that Withering had introduced the foxglove for dropsy, but most of us did not read far enough along in his remarkable book to get to the page where he gave advice as to the exact dose.

Bonetus, who as far back as 1679, compiled huge volumes of autopsy case reports, arranged according to symptoms from the top of the head to the soles of the feet, was one of the early forerunners of Cabot in differential-diagnosis case teaching. In these volumes, still largely untranslated, many interesting conditions can be read about, such as sudden death in a robust middle-aged man with aortic stenosis, a phenomenon that has again in recent years aroused special interest. Morgagni nearly a century later did of course present again many of the cases cited in the *Sepulchretum* of Bonetus, with valuable commentaries on their pathological significance, but there are still gems in this mine that may be rediscovered.

Osler, in the original edition of his *Practice of Medicine* of forty-five years ago, pronounced some views that we now think are rather newly held. For example, under rheumatic fever he writes that chorea is more apt to develop in the relatively slight rheumatic attacks of childhood, that rheumatic nodules may be regarded as a positive indication of rheumatism and have been noted particularly in severe and chronic rheumatic endocarditis, and that "medicines have little or no control over the duration or course of the disease, which like other self-limited affections practically takes its own time to disappear. Salicyl compounds, which were regarded so long as specific in the disease, are now known to act chiefly by relieving pain. Nor do they prevent the occurrence of cardiac complications."

And so it goes. The more one reads the better medical works of past generations, the more astonished one becomes, and the more humble, too, at what has been known and written and then forgotten. Progress has, after all, been very gradual with its ups and downs, though latterly much accelerated by the energetic activity of many workers. Yet in our zeal and enthusiasm at the present day we must not overlook the work and the ideas of our predecessors. We may perhaps rightly overthrow some of the teachings of our own teachers, only to find that their teachers in turn had believed some of the things that we believe today, perhaps

Conan Doyle, and the essays of Osler, Cabot and Cushing

The patient's reading must not be forced. The first rule is that it be for pleasure, and the physician can even profitably express to his patient his envy of the leisurely opportunity for reading that will come in convalescence or in prolonged illness—an opportunity that some over-busy physicians secretly look forward to, if only they may select their own illnesses!

And now, in closing, I wish long life and great usefulness to the Gerrish Memorial Library in its service to the doctors in Maine. May its books and journals play their part in keeping the medical profession in this State abreast of the times. May the library help in bringing solace and pleasure to both patients and doctors, and even kindle some susceptible spirits to add their own contributions to literature as well as to medicine.

GRANULOCYTOPENIA

Report of a Case with Autopsy

CHRISTOPHER C. SHAW, M.D.*

BELLOWS FALLS, VERMONT

GRANULOCYTOPENIA is characterized by a marked reduction in the number of circulating white blood cells, especially the polymorphonuclear leukocytes, with resultant impairment of the defense mechanism of the body against infection. Subsequent invasion of the respiratory and gastrointestinal tracts by the resident bacterial flora produces ulceration and necrosis. The onset of this disease may be insidious, its course dramatic and the outcome rapidly fatal. A somewhat similar clinical picture may be seen in overwhelming sepsis with extreme reduction of the white blood cells. The treatment and prognosis of the two syndromes are the same. The following case is probably of the latter sort.

CASE REPORT

D. J., a 64-year-old female, was first seen on October 6, 1936, when she requested a series of prophylactic inoculations against the common cold. She stated that she had arthritis and "heart trouble," and that she had been hospitalized on several occasions during the previous year. No satisfactory progress had been made and she had consulted a physician in another community, who had advised her to have her teeth extracted. This was done during the spring of 1936, but the arthritic pain continued, and sometimes she noted a swelling of the ankles at the end of the day.

The patient refused a general physical examination, so that a satisfactory history was not obtained. She weighed 201 lb, the blood pressure was 170/96 and the pulse rate 100. The heart sounds were essentially normal, and there was only slight edema of the ankles. The patient was given a reduction diet and advised to report at weekly intervals for the desired inoculations.

On that day she was given 4 minims of a stock coryza vaccine subcutaneously without reaction. A week later the dose was increased to 6 minims, and on October 20, 6 minims were again administered. The blood pressure on October 20 was 160/86, and the weight was 197 lb. The urine was negative for albumin and sugar,

and microscopic examination of the sediment showed nothing remarkable.

Eight hours after the last inoculation with the vaccine the patient had a severe chill and was somewhat cyanotic. She was very apprehensive but complained of no pain. She was put to bed and given 10 minims of adrenalin to combat the chill and 1 gr. of phenobarbital to allay her apprehension. The following morning there was a slight elevation of the temperature and pain in the lumbar region. Examination of the urine revealed from 15 to 20 pus cells per high power field, with several small clumps of leukocytes and an occasional red blood cell in the sediment. On the basis of these findings a diagnosis of pyelitis was made and the patient was seen daily for the next 7 days. She responded well to bed rest and conservative measures, and was discharged as cured on October 27.

Five days later (November 1) I was called to see her in the middle of the night because of nervousness and general malaise. She said that she did not feel well and wanted to make sure that nothing was wrong. The physical findings were essentially normal and the patient did not appear ill. No blood count was done at that time.

On the morning of November 4 I found the patient slumped in her chair in an exhausted condition, complaining of sore throat. It was at once apparent that immediate hospitalization was imperative. On admission to the hospital the temperature was 102.4°F, the pulse rate 100 and the respirations 22. The white-blood-cell count was 8150, with 71 per cent neutrophils and 16 per cent small lymphocytes. The erythrocyte count was 4,000,000, and the hemoglobin 75 per cent. The patient was quite weak and complained of being chilly. The mouth was dry and the throat sore. Examination revealed several areas of shallow ulceration involving the mucous membrane of the posterior pharyngeal wall, tonsils and fauces. The lungs were clear, the heart normal, and the blood pressure 142/70. The remainder of the physical examination showed an essentially normal condition, except that the patient appeared unduly toxic. Throat smears and cultures were negative for diphtheria bacilli, but revealed many other organisms. She was given the usual routine treatment for tonsillitis and pharyngitis, but complained of progressive soreness in the throat and marked dysphagia. At 4 o'clock that afternoon the temperature had risen to 104°F, the pulse rate was 88 and the respirations were 28, but the white-cell count had dropped to 5400, with 40 per cent neutrophils and 50 per cent small lymphocytes.

*Presented at the annual meeting of the Vermont State Medical Society at Saint Johnsbury, Vermont, October 14, 1937.
Preceptor in medicine, University of Vermont Medical School, Burlington, Vermont.

Osler's *Practice of Medicine* of 1892, and Cushing's *Life of Osler*, published in 1925

A classical education, spurned by many of the scientists and professional workers of today, has other values than those of the writing of better books and of pleasure in their reading, it adds enormously to the enjoyment of life and to its richness with the passing of the years. Even Greek, which is now so little studied, not only eases the lot of the first-year medical student as he memorizes many new anatomical names, but affords a foundation of the study of the history of medicine which has a practical as well as an esthetic value. It also greatly increases the enjoyment and profit of a visit to the medical shrines of Greece, which I myself most heartily recommend to any physician, young or old.

There remains the neglected topic of literature as medicine. We are all conscious of the possible importance of this method of psychotherapy, but we apply it very little, allowing our patients to read an enormous amount of absolute trash. Some reading matter of this description may be permitted on the basis of its soporific or distracting quality, but most of it were better consigned to the fire and replaced by something really worth while which can continue to be enjoyed through a lifetime. The text of Dr Gerald Webb's delightful address delivered before the Association of American Physicians in 1930 is one of the very few writings on this interesting subject.

I advise you to reserve a shelf or two of your library for books which have an outstanding value in convalescent care and in the treatment of nervous prostration, mental depression, chronic invalidism and incurable disease. I do not refer so much to books especially written for patients as to classical literature that delights the mind, absorbs the attention, and cheers the spirit of the healthy as well as that of the sick. What books are especially adapted for this? Which ones may lead the patient to new interests as well as to help him to pass the time enjoyably? In our own New England flowering of one hundred years ago there were two authors whose books belong here: Thoreau and Emerson. There are also Holmes's *Breakfast Table* series and the works of Mark Twain. For the beginning of convalescence there may be read snatches from Burns or Kipling. Soon after, the mind may be completely transported by James Hilton's most delightful story *The Lost Horizon*, *John Brown's Body* by Stephen Vincent Benét, or *Memoirs of a Midget* by Walter de la

Mare. Still later, the novels of Conrad, Dickens, Victor Hugo or Charles Reade, Chesterton's "Father Brown" or Doyle's Sherlock Holmes series may be prescribed with telling effect, not to mention such biographies as Strachey's *Queen Victoria* and *Eminent Victorians*, the essays of Lamb and Irving and the poetry of Coleridge, Wordsworth, Shelley and Keats. For more robust minds, at the end of convalescence or in chronic illness, Ortega's *The Revolt of the Masses*, Gibbon's *Decline and Fall of the Roman Empire*, Prescott's *Conquest of Mexico*, Galsworthy's *Forsyte Saga*, *South Wind* by Norman Douglas, and the works of Browning and Shakespeare, for young persons Stevenson and *Robinson Crusoe*, Mark Twain, *Alice in Wonderland* and *Dr Dolittle's Voyages*. Always one must judge the strength, mental age and interests of his patients. Some of these will do well in late convalescence or chronic illness to indulge in essays and articles dealing with fundamental aspects of the arts and sciences, but it is well not to force such books too soon.

I refer you especially to four passages of sound literature as examples of what may be used to entertain, divert and instruct the mind during convalescence or chronic illness. The first two, by writers of the past, are three paragraphs from Emerson's essay on Shakespeare, written in 1850, beginning "Great men are more distinguished by range and extent than by originality," "So it fares with the wise Shakespeare and his book of life," and "Shakespeare is as much out of the category of eminent authors as he is out of the crowd," and the first few pages of Shakespeare's *Julius Caesar*. The latter two, by authors of our own generation, are the first four stanzas of Benét's *John Brown's Body*, and a bit from T. E. Lawrence's *The Seven Pillars of Wisdom*, at about the middle of the book, describing the comments of Nasir, Mohammed, Zaal and Auda on the stars.

Let the doctor eventually pick out a "five-foot shelf" of books for therapeutic use, and read them himself. To do so will add to the pleasure of his life, the cultivation of his mind, the easing of strain and the effectiveness of his treatment—goals which are infinitely worth while, even though the patients themselves do not receive the books until they have become shopworn at the doctor's bedside.

Finally, in this collection of literary medicine set aside for professional interest there should be a special group consisting of the worth-while books that doctors themselves have written: the romances of Gargantua and Pantagruel by Rabelais, the writings of Oliver Goldsmith and Thomas Browne, the works of Oliver Wendell Holmes and S. Weir Mitchell, the detective stories of

*I have not included among the works cited below certain passages from the Bible despite their important place in literature and beauty of thought for those already familiar with the Scriptures; however, and for others needing spiritual consolation there are many passages from both Old and New Testaments that may be recommended particularly from the Psalms and from Christ's sermons.

and by Schwartz, Garvin and Koletsky⁵ and Berg and Holtzman⁶ in this country.

It has now been definitely established by extensive animal experimentation that benzene, or a benzene compound, is the one drug which will consistently produce a profound depressant action on the myelopoietic system. Kracke and Parker⁷ have demonstrated that aminopyrine and its derivatives will break down on oxidation into a double benzene ring, and if this oxidation process is carried far enough it will yield a pyrazolon derivative similar to phenylhydrazine, which in turn produces an aplasia of both the red and the white blood cells of the bone marrow. Kracke and Parker have further postulated that aspirin and other drugs of this series do not break down into oxidation products and are therefore relatively nontoxic. They cite numerous cases of agranulocytosis following the ingestion of aminopyrine alone or in combination with other drugs, and publish a list of forty-six such compounds which have been condemned by the Council on Pharmacy and Chemistry of the American Medical Association. Unfortunately this list does not include numerous patent medicines and secret formula remedies which are advertised widely to the laity through the newspapers and magazines and over the radio. The aminopyrine content of these nostrums is not known, or at least is not divulged either to the practicing physician or to the public, and there is as yet no readily available method of determining the hypersensitivity of a patient to such compounds before administration of the drug.

The distribution of these proprietary remedies—aminopyrine and sulfanilamide—has become world-wide, and coincident with their popularity the disease agranulocytic angina has been reported with increasing frequency throughout the so-called civilized countries. It was first described in Germany in 1922 by Schultz⁸ and in the United States in 1924 by Lovett.⁹ Kupper¹⁰ found only two earlier reports in the literature suggestive of agranulocytic angina, those of Brown and of Türk. In 1902 Brown¹¹ reported a "Fatal Case of Acute Primary Infectious Pharyngitis with Extreme Leukopenia," and in 1907 Türk¹² presented an article on "Septic Disease with Atrophy of the Entire Granulocytic System."

During the past fifteen years there has been a deluge of case reports of agranulocytic angina. This disease occurs mainly in women of middle age, it has become especially prominent among the upper social classes, who apparently tend to consume large quantities of proprietary medicines containing aminopyrine or sulfanilamide, and unfortunately is found all too frequently in members of the medical and other professions.

The symptoms of agranulocytosis are due to sepsis resulting from a marked diminution or even total absence of granular leukocytes in the circulating blood. This results in a loss of cellular resistance and the advent of infectious processes of various types, often fulminating in character. Two clinical types of the disease have been described—the acute and the chronic. In the acute type, similar to the case reported herein, there is a sudden onset of malaise accompanied by sore throat and fever. The progress of the disease may be very rapid. The malaise develops into a toxemia, the elevation of temperature into a hyperpyrexia and the sore throat into ulceration, necrosis and gangrene of the mucous membranes of the respiratory, gastrointestinal and genitourinary tracts. In such cases death may ensue in from twenty-four to forty-eight hours after the onset of the symptoms, and the blood count reveals a rapidly progressive and malignant type of neutropenia.

In the chronic form the first symptoms noted are usually a feeling of malaise, weakness and mild prostration, accompanied by chills, headaches and pain in the joints. These may be followed in a few days by a slight scratchy feeling in the throat, and an elevation of the temperature by a degree or two. The most common complaint in such cases is fatigue and exhaustion and it may well be that many middle-aged women who complain of being tired are actually suffering from a low-grade granulocytopenia. If the condition becomes progressive some degree of secondary anemia may appear in the chronic cases. Nerve pain may develop and the patient may gradually lose weight. Symptoms of functional nerve disease often confuse the clinical picture. The sore throat becomes very recalcitrant to treatment and in due course of time ulcerations may appear on the tongue, tonsils, fauces and posterior pharyngeal wall with intractable halitosis. The patient's general condition appears alarming as cachexia or a blood-stream infection sets in.

Blood counts taken during the course of such a malady reveal a progressive leukopenia, with a marked diminution of the neutrophilic percentage. In the chronic form remissions and exacerbations are the rule, and many patients have survived previous mild attacks only to succumb to a subsequent acute relapse complicated by a blood-stream infection, terminal pneumonia or fatal hemorrhage. Occasionally meningitis develops or a multiple peripheral neuritis makes the patient's condition unbearable.

The diagnosis of granulocytopenia (agranulocytosis) is based on the interpretation of the differential blood counts, which must be made in order to differentiate primary agranulocytosis, aleukemic

On the basis of this progressive leukopenia and the presence of the pharyngeal ulceration, a diagnosis of granulocytopenia associated with overwhelming sepsis was established. An attempt was made to obtain Pentnucleotide for intramuscular injection, but none was available until the following morning. In the meantime there was marked progression of the toxemia, and it was thought best to administer a foreign protein in an attempt to produce a leukocytosis. Accordingly 5 cc. of Proteolac was administered intravenously, and this dose was repeated at 4 hour intervals intramuscularly. In addition 10 cc. of whole blood was injected into the buttocks that evening. There was little if any favorable reaction, however, and the following morning (November 5) the temperature was 105.6°F, the pulse rate was 92 and the respirations were 34. The white cell count had fallen to 560, with 17 per cent polymorphonuclear leukocytes and 80 per cent small lymphocytes. The nonprotein nitrogen was 41 mg per cent. The throat showed numerous ulcerations, spotted by a grayish membrane, which also covered the base of the tongue. The patient was unable to swallow food or saliva and drooled continuously. She was extremely toxic, and her condition appeared critical. She was therefore given intravenous glucose, saline by hypodermoclysis and a transfusion of 200 cc of citrated blood. Following these measures the temperature fell to 103.8°F, but early that afternoon there was a rise to 106°F with a pulse rate of 120.

In spite of the administration of 10 cc. of Pentnucleotide every 4 hours during the 2nd day in the hospital, the patient rapidly became moribund. At 5 o'clock on the afternoon of November 5 the white cell count was 750, with 17 per cent neutrophils and 82 per cent small lymphocytes. During the evening the patient developed pulmonary edema and auricular fibrillation, which could not be controlled by rapid digitalization. She went rapidly downhill and died at 3:38 a.m. on November 6, approximately 48 hours after the onset of symptoms.

An autopsy was performed 4 hours after death, an abstract of the protocol follows.

The body was that of a middle-aged white female. There was a moderate degree of rigor mortis and the skin was sallow. There was a scar of a previous surgical incision in the low midline of the abdomen. A small ecchymosis due to administration of medication was present on the right thigh. The adipose tissue appeared very soft and mushy.

The lungs were air-containing throughout, and there was no free fluid in either pleural cavity. Numerous fibrous adhesions were present at the pulmonary apices. The heart appeared essentially normal on gross examination. Atheromatous changes to a moderate degree were present at the root of the aorta. The mediastinal structures were essentially normal. The liver was especially large, but unfortunately there was no opportunity either to weigh or to measure this organ at the place where the autopsy was performed. The spleen presented an acute red tumefaction. The stomach, pancreas and intestines showed nothing unusual. The uterus showed senile atrophy, and both ovaries were absent, having been removed at a previous operation. The kidneys presented cloudy swelling and several old cysts in the cortex. The bone marrow of the femur was soft, pale and mushy, while the bone marrow of the rib was replaced by fatty tissue.

Examination of microscopic sections of the various organs confirmed the above findings of an aplasia of the bone marrow, acute splenic tumor, fatty infiltration of the liver and moderate arteriosclerosis. Sections of the bone marrow of the femur showed very little hematopoietic

tissue, and the blood forming islands that remained intact presented a majority of myeloblasts and myelocytes. Only one or two neutrophilic metamyelocytes were noted in the entire section, and no mature polymorphonuclear leukocytes were seen.

This case of granulocytopenia is reported in some detail because of its dramatic clinical course and because a postmortem examination was made. The pathologic lesions in this case were probably caused by sepsis, which produced the profound neutropenia or granulocytopenia that is typical of such a bone-marrow dyscrasia. In these cases, lymph-node and splenic enlargements are fairly common, while ulcerations of the buccal cavity and along the mucous membrane of the intestinal tract are quite characteristic. Jaundice and thrombosis of the small arterioles, accompanied by perivascular hemorrhages, are usually seen in sepsis. The complications are numerous and include such conditions as thrombophlebitis, septicemia and terminal hemorrhage, although the last-mentioned mode of exitus is rare. At necropsy, pneumonia of either the lobar or lobular type may be present, and toxic degenerative changes are commonly found in the brain, heart, liver, adrenals and kidneys.

The bone marrow at autopsy presents a primary hyperplasia of the stem cells of the myeloid series with an absence of the mature granulocytes. This is thought to be due to an arrest of the maturation of the granulocytes. The early cell forms of the myeloid series proliferate abundantly, but fail to reach maturity, probably owing to the inhibitory action of some toxic agent (overwhelming sepsis) or of some allergic action (drug idiosyncrasy) on the myeloid cells. Moreover, the inhibitive or toxic factor is selective, and confines its action to the immature myeloid cells, since the erythropoietic tissue of the marrow remains unharmed. Erythroblasts, megakaryocytes, blood platelets, lymphocytes and monocytes show no pathologic changes.

The chief etiologic agents which have been found responsible for initiating this arrest of the normal maturation of the polymorphonuclear leukocytes are aminopyrine, dinitrophenol, gold salts and organic arsenical compounds. However, there are numerous cases on record in which no history of ingestion or administration of these drugs can be obtained. It would appear, therefore, that the disease may develop in certain instances without any apparent cause. During the current year, Hench¹ has put on record a case of agranulocytosis which resulted from the administration of sulfanilamide, a popular benzene derivative, para-aminobenzene sulfonamide. More recently, fatal granulocytopenia from sulfanilamide has been reported by Borst,² Model³ and Young⁴ in England.

THE RELIEF OF PAIN IN CANCER

JOHN S. HODGSON, M.D.*

BOSTON

IN CANCER the treatment of pain occupies an important place. The measures adopted, whether radiologic or surgical, radical or palliative, are often directed against both pain and disease. They are necessarily supplemented by the more or less widespread use of sedatives. In the majority of instances, even when cure has not been effected, the pain may thus be controlled. There are still, however, a considerable number of patients whose pain continues to be unrelieved in this manner. To this group, a variety of neurosurgical procedures can be applied with benefit, though this benefit may be only partial or temporary. As one's experience in dealing with such pain widens, the need of treatment becomes more obvious. One comes to feel also that treatment should be applied earlier in the disease, a short life expectancy is not necessarily a contraindication.

REFERRED PAIN

Some understanding of the mechanism of referred and radiating pain is essential for the accurate determination of its point of origin. This is true not only of lesions of the face, mouth, throat, head, neck and shoulder, which may be visible, but also and especially of the more deeply seated or concealed lesions in the viscera or parietes. Growths involving the anterior two thirds of the tongue and floor of the mouth may cause pain to be referred to the temporal region, the ear or the top of the head. Face and scalp pain follows the course of the auriculotemporal branch of the mandibular or third division of the fifth nerve. Ear pain may be referred along the tympanic branch of the glossopharyngeal nerve. With involvement of the upper alveolus, palate, antrum and upper part of the face, the pain may be local and be referred from the malar or zygomatic region part way around the orbit (zygomaticotemporal branch of the second division of the fifth cranial nerve). With disease of the posterior third of the tongue, fauces or pharynx, pain is commonly referred to the lower throat and ear, and may be aggravated by swallowing.

In disease of the cervical lymph nodes, if in the anterior triangle, the pain is local and may also be referred in front of or to the ear, if in the posterior triangle, the reference is to the posterior part of the neck and scalp.

SENSORY NERVE SUPPLY OF THE HEAD AND NECK

The sensory elements involved in head and neck pain are the trigeminal, or fifth, the glossopharyngeal, or ninth, and the vagus, or tenth cranial nerve, the upper five posterior cervical nerve roots, and, to an extent as yet undetermined, the sympathetic ganglia or plexuses.

The trigeminal nerve supplies sensation to most of the face as well as the scalp two thirds of the way back to the occiput, a portion of the outer upper part of the external ear, most of the tongue,—the anterior two thirds,—the floor of the mouth and palate, the eyeball and, with the aid of the sphenopalatine ganglion, the accessory air sinuses.

The glossopharyngeal nerve supplies, along with the vagus and sympathetics, the pharynx, the posterior third of the dorsum of the tongue, one half of the sides of the tongue, part of the soft palate, part of the faucial and tonsillar regions, the eustachian tube, the tympanic cavity, the inner surface of the eardrum and the mastoid cells.

The vagus nerve by its sensory connections is said to supply the skin of the posterior part of the auricle and the posteroinferior portion of the external auditory meatus, part of the external aspect of the eardrum, the pharynx in conjunction with the glossopharyngeal and the superior cervical sympathetic fibers, part of the base of the tongue, and the internal surface of the larynx (superior laryngeal nerve).

The upper five cervical posterior nerve roots supply, through the greater and lesser occipitals, the great auricular and lateral superficial cervical nerves, the skin and subcutaneous tissues of the lower part of the face, a considerable part of the external ear, the neck to below the clavicle in front, to the spine of the scapula behind, and externally to about the deltoid insertion, in addition to the posterior part of the scalp for one third the distance toward the forehead, meeting there the area supplied by the fifth nerve.

The salivary glands and the superficial and deep cervical lymph nodes receive their nerve supply from cranial, spinal and sympathetic nerves. The three large salivary glands are supplied by branches from the trigeminal nerve and from the cervical sympathetics.

NEUROSURGICAL MEASURES EMPLOYED

Broadly speaking, the neurosurgical measures employed to relieve pain comprise, in order of

Read before the annual meeting of the New England Surgical Society, October 2, 1937 at Providence, Rhode Island.
Neuro-surgical to State Cancer Hospital at Pondville

leukemia and aplastic anemia. If a history of administration of aminopyrine can be obtained, the problem of diagnosis is much easier, the age and sex of the patient should also be borne in mind. In short, the differential diagnosis of the leukopenic states requires great care in interpretation of the blood pictures and clinical findings in order to avoid misjudgment of the underlying lesions. It is obvious that not all cases of leukopenia are of the essential or primary type, nor are they related to granulocytopenia, malignant neutropenia or agranulocytosis.

The prognosis is poor in the acute type of the disease, in which the mortality in untreated cases averages between 75 and 85 per cent. In the chronic form the outlook is not good. Many cases may recover spontaneously upon withdrawal of the offending agent, only to develop a fatal recurrence at some future time. The appearance of eosinophils in the blood smear and a progressive increase in myeloblasts, neutrophilic myelocytes and neutrophils both point to a favorable prognosis.

Treatment of this disease resolves itself into four or five procedures. Pentnucleotide in sufficiently large doses—from 40 to 50 cc daily—acts almost as a specific in initiating bone-marrow activity in the primary leukopenias. Prompt improvement following the intramuscular administration of nucleic acid derivatives coincides with the myelocytic response, and in a sense parallels the reticulocyte response during recovery from pernicious anemia. Adenine sulfate, another nucleic derivative, may be given intramuscularly or intravenously with good effect. The parenteral administration of liver extract and transfusions of either whole or citrated blood may be of some value as a general systemic and hematopoietic tonic, but they are not specific for this disease. Gordon¹³ recommends injection of 40 cc of whole blood intramuscularly twice a day in order to produce an irritation of the muscle tissue and thus stimulate the bone marrow. Foreign proteins are useless. Intravenous dextrose and saline solution should be administered when the pharyngitis produces dysphagia and edema. Bland mouth washes and oral hygiene are indicated in the chronic forms of this disease. A high-nuclein diet, together with dietary components rich in vitamin G, has been recommended. It is obvious that supportive measures similar to those employed in any infectious process are indicated.

Unfortunately the therapy of granulocytopenia is far from satisfactory, and many of the patients with acute fulminating forms of the disease die regardless of the treatment employed. Nevertheless,

the judicious and adequate administration of Pentnucleotide both intravenously and intramuscularly has reduced the mortality from 80 per cent to approximately 25 per cent. Recovery seems to depend on early diagnosis and immediate and massive therapy. Not less than 40 cc of Pentnucleotide should be given in a day. The most logical form of treatment is prevention, and it is obvious that once the diagnosis is made no product containing aminopyrine or sulfanilamide should be administered.

5 School Street.

DISCUSSION

Dr. E. L. Amidon, Burlington, Vermont: Dr. Shaw has given us an excellent review of agranulocytosis. I cannot do better than add some data collected at the Mary Fletcher Hospital. His case differs from our cases in that his patient had sepsis, mouth lesions, a temperature of 102.4°F and a white-cell count of 8150 and 71 per cent neutrophils. In our experience the sepsis follows the leukopenia rather than the reverse.

All the cases of Vincent's angina, gingivitis, stomatitis, aleukemic leukemia and aplastic anemia received in the Mary Fletcher Hospital have been reviewed and checked. No case of agranulocytosis was seen prior to the year 1927. During the last ten years we have had 8 cases, 7 during the last four years. The first case terminating fatally was that of a physician, the blood smears at one time revealed no granulocytes. None of the physicians who saw this case had ever before observed such a state. All but 1 of our patients had taken an analgesic drug, or had had a history of some painful ailment which might have indicated such treatment.

Of the 8 patients with agranulocytosis, 6 received Pentnucleotide. Two died and 2 showed definite improvement in the blood before the drug was given, leaving only 2 in whose cases Pentnucleotide could have been helpful.

We have recently had a patient suffering from agranulocytosis following the administration of 1000 gr of sulfanilamide during a period of fifty days. The drug was removed, and he was given yellow bone marrow extract. His recovery was abrupt, and was complete in ten days.

Intracranial Operations

When the cancerous process is extensive, but involves only the branches of the fifth nerve, and if the patient's condition permits, intracranial section of the root of the fifth nerve is desirable. The section may be total, or may spare the ophthalmic division and motor root. Intracranial section of the third or the second branch, performed extradurally, is sometimes done also. The posterior root of the fifth nerve may be sectioned by either the temporal or the occipital (cerebellar) route. I prefer the former when it is feasible—that is, when it is not prevented by disease or infection in or near the operative field, and I believe it to be safer. If, however, the disease process and the pain caused by it involve adjoining areas which are supplied by both the fifth cranial and the upper cervical nerves, the cerebellar approach may be better, particularly if it is desired and is thought safe to combine a craniotomy with a laminectomy—that is, an intracranial and intraspinal section at the same operation. But this procedure cannot be tolerated in many instances of advanced cancer, such as we see at the Pondville Hospital, for example, although I have adopted it in a few cases.

Intracranial section of the ninth or glossopharyngeal nerve is sometimes done to relieve deep throat and ear pain due to cancer in the posterior tongue throat or pharynx. This operation is done by the cerebellar route, and is not difficult—considerably less so than that of division of the fifth nerve through this approach. This procedure is helpful but it does not always give complete relief, as we are probably also concerned in such cases with vagus and sympathetic nerves. It is ordinarily impracticable to section the ninth nerve in the neck. Rarely, in the presence of extensive disease, areas supplied by the fifth, ninth and upper cervical nerves may all be involved. In certain of these cases, intracranial section of the fifth and ninth nerves, combined with additional intraspinal section of the cervical nerves from the first to the fifth, inclusive, has been done at the same operation. I myself have not done this.

Intraspinal Operations

Cervical laminectomy and posterior-root section (rhizotomy) This operation is one that I have had many occasions to perform, I find it useful in the presence of disease in the neck giving rise to pain in the lower part of the face, neck and posterior scalp. A laminectomy—sometimes on only one side—extending from the first to the fourth cervical vertebra is performed. The first four or five posterior nerve roots on one side are then cut or crushed. The relief from neck pain is sat-

isfactory, and patients stand the operation fairly well.

Chordotomy The value of chordotomy, an operation first suggested by Spiller in 1911, was first fully demonstrated by the late Dr Charles H Frazier in 1920. It was at first used to relieve intractable pain below the upper part of the body. The operation was done at about the level of the fifth thoracic segment or the third dorsal vertebra. Since then it has been shown that in order to relieve deep pressure pain as well as superficial pain,—in the lower extremities, for example,—the operation must be carried as high as the third thoracic segment, that is, the first dorsal vertebra to include all pain fibers coming from the lower extremities. To relieve arm pain, the chordotomy should be done at the sixth cervical segment or the fifth cervical vertebra.

Chordotomy—section of the spinothalamic anterolateral columns—cuts across the pain-fiber tracts. The section is made on the side of the spinal cord opposite the limb or side of the body involved by pain. The pain fibers, after entering the spinal cord on its dorsal aspect in the posterior root, cross the commissure at once or within one or two segments to the opposite side of the cord and ascend in the anterolateral column of that side to the thalamus and thence to conscious levels of perception in the brain cortex. This column lies anterior to the pyramidal tract and the temperature fibers. To reach it, a fairly wide laminectomy is performed, preferably under local anesthesia, so as to be able to test immediately for a satisfactory level of analgesia. The dura is opened and the arachnoid incised laterally. A dentate ligament, which is a lateral prolongation of the arachnoid to the dura placed halfway between the anterior and posterior nerve roots, is cut at its dural attachment, and by traction upon it the cord is rotated so as to expose the anterolateral aspect on the side opposite the pain. A specially devised Frazier hook or a sharp-pointed knife blade is then inserted into the spinothalamic tract to a depth of from 3.5 to 5 mm just anterior to the attachment of the dentate ligament to the cord. The blade is brought from within outward and emerges at an anterior root. Immediate and complete relief from pain is obtained. This can be verified by testing for analgesia, both superficial and deep. If a bilateral chordotomy is done, there should be a difference of about a segment in the level of the sections in order to avoid interference with cord circulation. Chordotomy may be carried out as high as the second or third cervical segment if done unilaterally, but it is dangerous to do it bilaterally because of possible injury to phrenic centers in this region. A high and a low

frequency, (1) peripheral injection of branches of the trigeminal or fifth cranial nerve with alcohol, (2) intraspinal subarachnoid alcohol injection, (3) chordotomy, (4) spinal posterior-root section—rhizotomy, (5) intracranial cranial-nerve section—trigeminal and glossopharyngeal nerves, and (6) peripheral-nerve section—superficial cervical, inferior dental and lingual nerves. Other procedures less often used are alcohol injection of the Gasserian ganglion, myelotomy and presacral-nerve section.

As is evident, the attack centers more directly on the central and peripheral nervous system than on the autonomic, except in case of the presacral nerve. Autonomic nerve fibers involved in visceral pain, however, are sectioned in the operation of chordotomy at higher levels, and to a certain extent in spinal posterior-root section.

GENERAL PRINCIPLES OF RELIEF OF PAIN

With pain in the head, neck and shoulders, one deals with cranial or spinal nerves and their branches. The severance of these nerves involves the sacrifice of touch as well as pain sensation in a given area, but results in no hardship to the patient. An exception to the limits set in this field of activity may rarely be made in the case of bilateral intractable neck or shoulder pain, in which neither nerve roots nor peripheral nerves, but rather the spinal cord, either across the spinothalamic tracts—anterolateral columns (chordotomy)—or the commissure, might be divided (myelotomy).

To relieve upper extremity pain usually requires cutting pain-fiber tracts in the spinal cord (anterolateral columns). This operation interferes principally with pain transmission and to some extent with temperature appreciation, but leaves essentially intact those fibers mediating touch, pressure and position—an important consideration in the arms and hands. An upper extremity devoid of all modalities of sensation is practically useless. For this region, therefore, posterior-root section is undesirable.

This same method applies on the whole to similar problems below the upper extremities, that is, to those affecting the body—chest, abdomen and pelvis—and the lower extremities. In other words, relief of pain, unless due to disease which can be recognized as very limited in extent, is best obtained by rendering the entire body or one side of the body analgesic, from well above the uppermost level of pain, by a relatively limited operative procedure on the spinal cord. To be sure, resort to posterior-root section will occasionally be made, as for example in a localized lesion, often visible by x-ray as a bony metastasis, causing limited pain.

Unilateral or bilateral posterior-root section, however, is as a rule a more extensive operation and is less certain to give relief. Preference over chordotomy may also be given to spinal subarachnoid injection if the patient's condition is poor and life expectancy very short, provided the diseased area comes within the supply of the roots of the cauda equina. In any case, the necessity for preserving intact the sensation of touch and position in the lower extremities is clear.

SPECIFIC MEASURES AND THEIR REGIONAL APPLICATION

Peripheral-Nerve Injection with Alcohol

Peripheral-nerve alcohol injection is largely confined to the area supplied by the fifth cranial nerve. In elderly or debilitated patients this is often the only method available where the pain is due to implication of one or more—usually the second or third—branches of the fifth nerve. Moreover, some patients, having already undergone extensive operations or radiation, refuse further surgery. The results of such an injection are often satisfactory, more so, I believe, where the second division of the nerve is involved. Disease involving the third-division supply is prone to extend downward into the lymph nodes of the neck to areas supplied by the cervical nerves, or backward into ninth-nerve territory. For this reason, third-division alcohol injection may give but partial relief. Nevertheless, alcohol injection of the second and third divisions singly or together is commonly done, and is distinctly worth while. The extraoral method should be employed. The area supplied by the first division of the fifth nerve is infrequently involved by disease causing severe pain, and alcohol injection is seldom used there. It may be tried, but its results are not particularly satisfactory. Alcohol injection is not used in ninth or tenth cranial-nerve pain, or in that involving cervical nerves.

Peripheral-Nerve Section
